Site History

- SWMU 4, the LWDS Surface Impoundments, is an approximately 80-acre site located northwest of SA-V.
- The LWDS was designed to receive and discharge radioactive effluent from the SEDF and other associated activities in Building 8300. The LWDS consists of five holding tanks (SWMU 1-5), the Drainage (SWMU 6), and the primary impoundment (SWMU 4). The SEDF operated from 1962 to 1971. Effluent from the SEDF was discharged to the LWDS. The LWDS was designed to receive effluent from the Drainage. The Drainage collapsed in 1967 and the surface impoundments were built to receive effluent from the SEDF.
- The impoundments received radioactive effluent until 1970, and continued to receive effluent from TA-V operations until 1982. From 1967 until 1970, the impoundments received approximately 12 million gallons of effluent containing approximately 14 curies of measured radioactivity.

Depth to Groundwater

- The regional aquifer is approximately 400 ft bgs.

Constituents of Concern

- VOCs
- SVOCs
- Metals
- PCBs
- Radionuclides

**SWMU 4
LWDS Surface Impoundments**

Summary of Investigations

- SWMU 4 site investigation began in 1982 and included a surface radiation survey, organic vapor surveys, and extensive surface soil sampling. A 10-yd by 10-yd grid was established and surface soil samples were collected from the center of each of 100 squares. Additional sampling was obtained from the surface and at a depth of 1 ft at the drainage ditches. Soil samples were analyzed at an off-site laboratory by VOCs, SVOCs, PCBs, metals, and radionuclides.
- In 1982, five soil borings (LWDS-BH01 through LWDS-BH05) were advanced from 65 to 100 ft bgs in locations around the surface impoundments. In 1984, four additional soil borings (LWDS-BH06, LWDS-BH07, LWDS-BH11, and LWDS-BH15) were advanced in locations within the surface impoundments. Continuous cores were collected from all the borings. Soil samples were collected at approximately 5-ft intervals and analyzed for TN, metals, VOCs, SVOCs, PCBs, Tritium, and radionuclides by gamma spectroscopy.
- In 1982, monitoring well LWDS-MW02 was installed north of the impoundments to a total depth of 531 ft bgs. This well is part of the TA-V facility monitoring well network and is sampled on a regular basis. Continuous monitoring of this well provides real-time data on the presence of radionuclides at approximately 5-ft intervals beginning at 160 ft bgs and submitted for laboratory analysis for VOCs, SVOCs, metals, and radionuclides.
- Analytical results revealed 17 metals detected above background values. PCBs were detected in a surface sample at 0.071 mg/kg (in Anovar 1260). Nine VOCs and seven SVOCs were detected. The radionuclides Co-137, Ra-226, Th-232, U-235, and Tritium were detected above background activities. Co-60 and Pb-210 were detected, but their are not background activities for comparison. There was a detection of U-238 that equated the background activity.

Summary of Data used for NFA Justification

- Data that was used for the final risk assessment and NFA justification included soil samples collected in 1982 from the surface of the impoundments and from borings, and soil samples collected from borings in 1984.

Recommended Future Land Use

- Industrial land use is established for this site.

Results of Risk Analysis

- Risk assessment results for the residential scenario are calculated per NMEQ risk assessment guidance in 2003 as presented in the "Residential Risk Document Supporting Class 3 Permit Modification Process" (SNL/AM October 2004).
- Because COCs were present in concentrations of activities greater than background screening levels or because constituents were present that did not have background screening levels, it was necessary to perform a risk assessment for the site. The risk assessment analysis evaluated the potential for adverse health effects for the residential land-use scenario.
- The total human health risk with 0.71 for the individual land-use scenario, which is less than the NMEQ production of 1. The total estimated excess cancer risk was 6E-6 for the industrial land-use scenario, which is less than the NMEQ guideline of 1E-5.

- The total human health risk with 0.36 for the residential land-use scenario, which is greater than the NMEQ production of 1. The total estimated excess cancer risk was 2E-5 for the industrial land-use scenario, which is greater than the NMEQ guideline of 1E-5. Using the USCL of the residential land-use scenario, the main contributors to risk (benzene, cadmium, and perchloroethene), the total risk was reduced to 2.10 and the low estimated excess cancer risk was reduced to 2E-6. The incremental risk and excess cancer risk are 1.89 and 2.00E-4. In addition, none of the individual HQs for noncarcinogens exceeded 1.0 under these conditions. Thus, the individual HQs and estimated excess cancer risk are below the NMEQ guidelines for a residential land-use scenario.
- The human health incremental TEQD for an industrial land-use scenario was 17 twenty, which is slightly higher than the EPA national guideline of 15 twenty for soil that the DOE's guideline of 20 twenty. The TEQD for an industrial land-use scenario was 17 twenty, which is below the EPA national guideline of 20 twenty. Therefore, SWMU 4 is eligible for unrestricted residential use.
- Using the SML ecological risk assessment methodology, the ecological risk for SWMU 4 is predicted to be low.

In conclusion, human health and ecological risks are acceptable per NMEQ guidance under a residential and/or industrial scenario. Thus, SWMU 4 is proposed for DAC without institutional controls. However, the NMEQ risk issued a certificate for DAC with institutional controls for this site.

Below table are maximum values for each constituent listed.

EXECUTIVE SUMMARY

Background

A significant portion of the nuclear design and engineering work performed at Sandia National Laboratories/New Mexico (SNL/NM) was conducted in Technical Area V (TA-V). The Liquid Waste Disposal System (LWDS) was designed to receive, monitor, and discharge radioactive effluent from the Sandia Experimental Reactor Facility (SERF) in TA-V. The LWDS consists of three holding tanks and an associated pumping system (Environmental Restoration [ER] Site 52), a drainfield (ER Site 5), and two surface impoundments (ER Site 4).

Starting in 1963, radioactive discharges drained to the holding tanks where they were monitored and then pumped into the drainfield. The discharge water washed away the soil near the drainfield. In 1967, the drainfield collapsed and would no longer accept water. Discharges were then directed into the impoundments. Radioactive discharges continued until 1971 when the SERF was decommissioned. From 1963 until 1971, the system received approximately 19 million gallons of waste water contaminated with approximately 35 curies of radionuclides. Nonradioactive discharges to the surface impoundments continued until 1992. Possible contaminants for all LWDS sites include radionuclides from the discharge of reactor cooling water, organic solvents/heavy metals from various industrial processes in TA-V, and polychlorinated biphenyls (from an unknown source in the LWDS surface impoundments only). Presently, the LWDS holding tanks discharge to a new TA-V Liquid Effluent Control System.

Investigation Work Plan

The LWDS investigation was performed in accordance with the *Liquid Waste Disposal System RCRA Facility Investigation Work Plan* (hereafter the "LWDS RFI work plan"). The investigation included collecting 80 surface soil samples and performing geophysical tests in the LWDS surface impoundments, drilling 16 boreholes, performing an internal investigation of the LWDS holding tanks and associated piping, and installing and sampling ground-water monitor wells at the LWDS surface impoundments and drainfield.

The LWDS RFI work plan has four basic objectives:

1. Define the nature and extent of contamination at each of the ER sites that comprise the LWDS,
2. Identify potential contaminant transport pathways,
3. Evaluate potential risks posed by the levels of contamination identified at the LWDS, and
4. Provide guidance for selecting remedial alternatives at the site, if necessary.

Data Evaluation

Data collected during the RCRA Facility Investigation (RFI) were evaluated several ways. Initially, a constituent population was statistically compared to natural background

using EPA-approved methods. Any constituent of concern failing the statistical comparison was further analyzed for its spatial distribution. Contamination at the LWDS demonstrated a strong spatial correlation with the discharge points, and the combination of statistical techniques with the use of process history provides a robust analysis. Constituents that failed the statistical comparison to background and showed a strong spatial correlation were identified as contaminants.

After a constituent was identified as a contaminant, the sample population was compared to RCRA proposed action levels and, in most cases, studied in a detailed risk assessment. A computer model developed by SNL/NM, called the Probabilistic Risk Evaluation and Characterization Investigation System (*Précis*), was used. The basic risk assessment methodology defined by the U.S. Environmental Protection Agency (EPA, 1989) has been modified to include a quantitative uncertainty analysis technique. The probabilistic risk assessment methodology is ideal for quantitatively assessing uncertainty. Site-specific sections list assumptions from the risk assessment methodology that relate to future land use and exposure unit definitions.

Results and Recommendations

In summary, contamination was detected at all three sites. Contamination levels are low, in most cases barely discernible above background, and are limited to the near surface of the LWDS surface impoundments, the vicinity of the LWDS drainfield, and inside the LWDS holding tanks. A detailed analysis of these contamination levels has been completed, and No Further Action is recommended for all three sites.

Trichloroethene and its degradation products are present in LWDS drainfield ground-water monitor well LWDS-MW1. These chemicals have not been detected in any LWDS ER sites and are most likely from another source area in TA-V. Further investigations of TA-V ground-water issues continue under the TA-III/V RCRA Facility Investigation.

1.0 INTRODUCTION

1.1 Site Background

A significant portion of the nuclear design and engineering work performed at Sandia National Laboratories/New Mexico (SNL/NM) was conducted in Technical Area V (TA-V). The Sandia Engineering Reactor Facility (SERF) located in TA-V consisted of a main reactor and experimental facilities housed in Buildings 6580 and 6581, and support facilities housed in Buildings 6582 and 6583 (Figure 1-1). Operation of these facilities resulted in the generation of industrial waste water, some of which contained low concentrations of radionuclides. The Liquid Waste Disposal System (LWDS) received and managed this waste water.

The LWDS consists of three holding tanks and the associated pumping system (Environmental Restoration [ER] Site 52), a drainfield (ER Site 5), and two surface impoundments (ER Site 4) (Figure 1-1). The LWDS received liquid effluent from the main reactor, experimental facilities, and support facilities in TA-V. The holding tanks received liquid effluent from the SERF during that facility's entire period of operation from 1962 to 1971. The drainfield was used from 1963 to 1967; it collapsed in 1967 and was replaced with the two surface impoundments. The impoundments were used to receive radioactive waste water from 1967 to 1971. Since 1971, the holding tanks have received nonradioactive waste water from the Hot Cell Facility (HCF) housed in Building 6580. The nonradioactive waste water was discharged to the impoundments until October 1992. Currently, the holding tanks drain to a new Liquid Effluent Control System (LECS). The LECS receives and holds all TA-V process water for sampling prior to discharge to the City of Albuquerque publicly-owned treatment works (POTW).

1.2 RFI Work Plan Overview and Objectives

All LWDS work has been performed in accordance with the *Liquid Waste Disposal System RCRA Facility Investigation Work Plan* (hereafter the "LWDS RFI work plan") approved by the U.S. Environmental Protection Agency (EPA), Region VI in 1994 (SNL, 1994a). The LWDS RFI work plan outlined an investigation strategy that included:

- Collecting surface soil samples at the LWDS surface impoundments;
- Performing surface geophysical tests at the LWDS surface impoundments;
- Drilling and sampling boreholes at the LWDS surface impoundments, drainfield, and holding tanks;

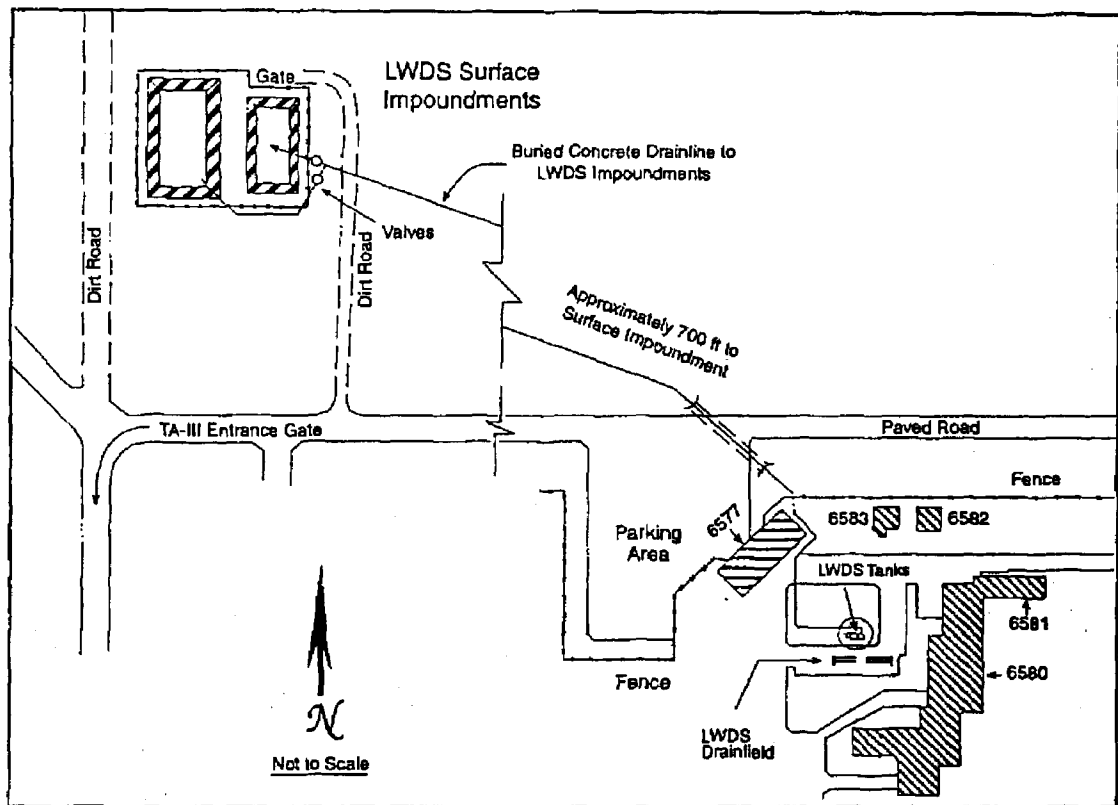

Figure 1-1. Liquid Waste Disposal System Site Map

- Performing an investigation of the LWDS holding tanks internal contents and associated piping; and
- Installing and sampling ground-water monitoring wells at the LWDS surface impoundments and drainfield.

The LWDS RFI work plan also described data analysis methods, including a comparison to background and health-based cleanup concentrations and activities.

In summary, there were four overall objectives of the LWDS RFI work plan:

1. Define the nature and extent of contamination at each of the three LWDS ER sites;
2. Identify potential contaminant transport pathways;
3. Evaluate potential risks posed by the levels of contamination identified, if present; and
4. Provide guidance for remedial alternatives at the sites, if necessary.

2.0 ENVIRONMENTAL SETTING

2.1 Climate

In general, the weather for Albuquerque and vicinity, including SNL/NM, is typical of high-altitude, dry continental climates. The normal daily temperature ranges from 23°F to 52°F in the winter months and from 57°F to 91°F in the summer months. The average annual relative humidity is approximately 46 percent; however, the relative humidity can range from a low of 5 percent to a high of 70 percent (Bonzon et al., 1974).

The average annual precipitation for the Albuquerque area is 8.54 in. The average monthly precipitation ranges from a minimum of less than 0.5 in. in the winter months to approximately 1.5 in. in the summer months. Mean annual snowfall in the Albuquerque area is approximately 11 in. Summer precipitation, particularly July through August, is usually in the form of heavy thundershowers that typically last less than 1 hour at any given location (Williams, 1986). Average annual pan evaporation at Albuquerque International Sunport weather station 224 is 89 in. (U.S. National Weather Service, 1982).

Under normal conditions, wind speeds seldom exceed 32 mph and are generally less than 8 mph (Bonzon et al., 1974). Strong winds, often accompanied by blowing dust, occur mostly in late winter and early spring. During these months, the prevailing surface winds are from the east. Rapid nighttime ground cooling produces strong temperature inversions and strong drainage winds down the Tijeras Canyon.

2.2 Surface Features

Cultural Surface Features

The LWDS holding tanks and drainfield are located within TA-V. TA-V, which encompasses approximately 23 acres, contains approximately 20 permanent structures and 30 temporary buildings and trailers. The LWDS holding tanks and drainfield were constructed below grade; as such, the only visible surface features are the accesses to holding tanks 2 and 4, and the tank vents.

The surface impoundments are located approximately 1000 ft northwest of TA-V (Figure 1-1). Except for monitor well LWDS-MW2, no permanent structures exist at the surface impoundments. The surface impoundments also were constructed below grade.

Impoundment 1 is approximately 8100 ft² with dimensions of 65 ft by 125 ft by 12 ft deep. Impoundment 2 is approximately 9400 ft² with dimensions of 102 ft by 92 ft by 20 ft deep. The original size may have changed slightly as a result of sidewall erosion and the subsequent deposition of the eroded soil on the impoundment floors.

The *Technical Areas 3 and 5 RCRA Facility Investigation Work Plan* describes other TA-V facilities in further detail (SNL, 1993).

Natural Surface Features

The LWDS is approximately 4 mi west of the Manzano Mountains and 7 mi east of the Rio Grande. Elevations at the LWDS range from 5400 ft above sea level at the surface impoundments to 5440 ft above sea level near the holding tanks. The immediate vicinity is a gently sloping plain.

2.3 Surface Water

Surface water is rarely present in the LWDS vicinity. During large rainstorms, surface water may pond in depressions that remain after grading operations within TA-V. After the storms, the ponds evaporate quickly.

2.4 Geology

2.4.1 Regional Geology

The Albuquerque-Belen structural basin is one of the largest north-south trending basins in the Rio Grande trough. The basin is a compound graben measuring 90 mi long and 30 mi wide, bordered by uplifted fault blocks to the east and west (Bjorklund and Maxwell, 1961). The eastern boundary is marked by the Sandia, Manzanita, and Manzano mountains. The western side of the basin is bounded by the Lucero uplift, with the Ladron Mountains to the south and minor physiographic relief to the northwest.

Erosion from the surrounding highlands has filled the Albuquerque basin with up to 9000 ft of sediments. This sequence of sediments, the Santa Fe Group Formation, consists of debris flows and channel, flood plain, and aeolian deposits. The Santa Fe Group thins toward the basin edges and is truncated by the bounding uplifts. The Miocene- and Pliocene-age Santa Fe Group sediments are interbedded with Tertiary and Quaternary basalts and pyroclastics, and are overlain in places by the Pliocene Ortiz gravel deposits and Rio Grande fluvial deposits (Bjorklund and Maxwell, 1961).

2.4.2 Local Geology

From August 1992 to May 1993, the U.S. Geological Survey (USGS) collected lithologic and hydrogeologic data beneath the LWDS during drilling operations. Information was collected from 16 boreholes and 2 ground-water monitor wells.

The sediments underlying the LWDS facility consist of alluvial fan deposits derived from the Manzanitas to the east. On a local scale, alluvial fan deposits are characterized by great internal variability, and detailed correlations are not feasible. On a larger scale, however, general trends can be observed laterally and vertically.

The borehole geophysical logs provide a continuous, normalized indirect measurement of the relative amount of "fines" in the sediment via the gamma-ray (GR) and neutron (N) curves. The GR log measures the natural radioactivity emitted primarily from the potassium-40 of the clays and the potassium feldspars. Increasing GR response (in counts per second) generally indicates an increasing percentage of fine sediments. The N log measures the relative concentration of the hydrogen (H) ion of water in the sediment, and because many clays contain chemically bound H in their crystal lattices, a decreasing N response generally indicates an increasing percentage of clayey sediments. Below the water table, the N becomes "saturated" and cannot be used for lithologic control. The generally increasing GR and decreasing N readings downward in both LWDS-MW1 and LWDS-MW2 wells (Figures 2-1 and 2-2) indicate the decrease with depth in average sediment grain size.

Continuous core was collected and described for LWDS-MW1 and soil samples were collected for grain-size analysis and saturated conductivity (K_{sat}) at 20-ft intervals. The results of these measurements and lithologic descriptions indicate that coarse-grained sediments dominate the upper section and that grain size decreases downward to approximately 490 ft and support the interpretation of the geophysical logs. The top of the section is dominated by high-energy episodic debris flows that deposited coarse-grained loads near the head of an alluvial fan derived from the eroding mountains to the east. As depth increases, the lithology indicates a more tranquil depositional environment at the toe of the alluvial fan. This lithologic variation is consistent with the regional depositional pattern of coarser material deposited over fine material

LWDS-MW1

Geophysical Logs USGS

LWDS-MW2

Geophysical Logs 1365

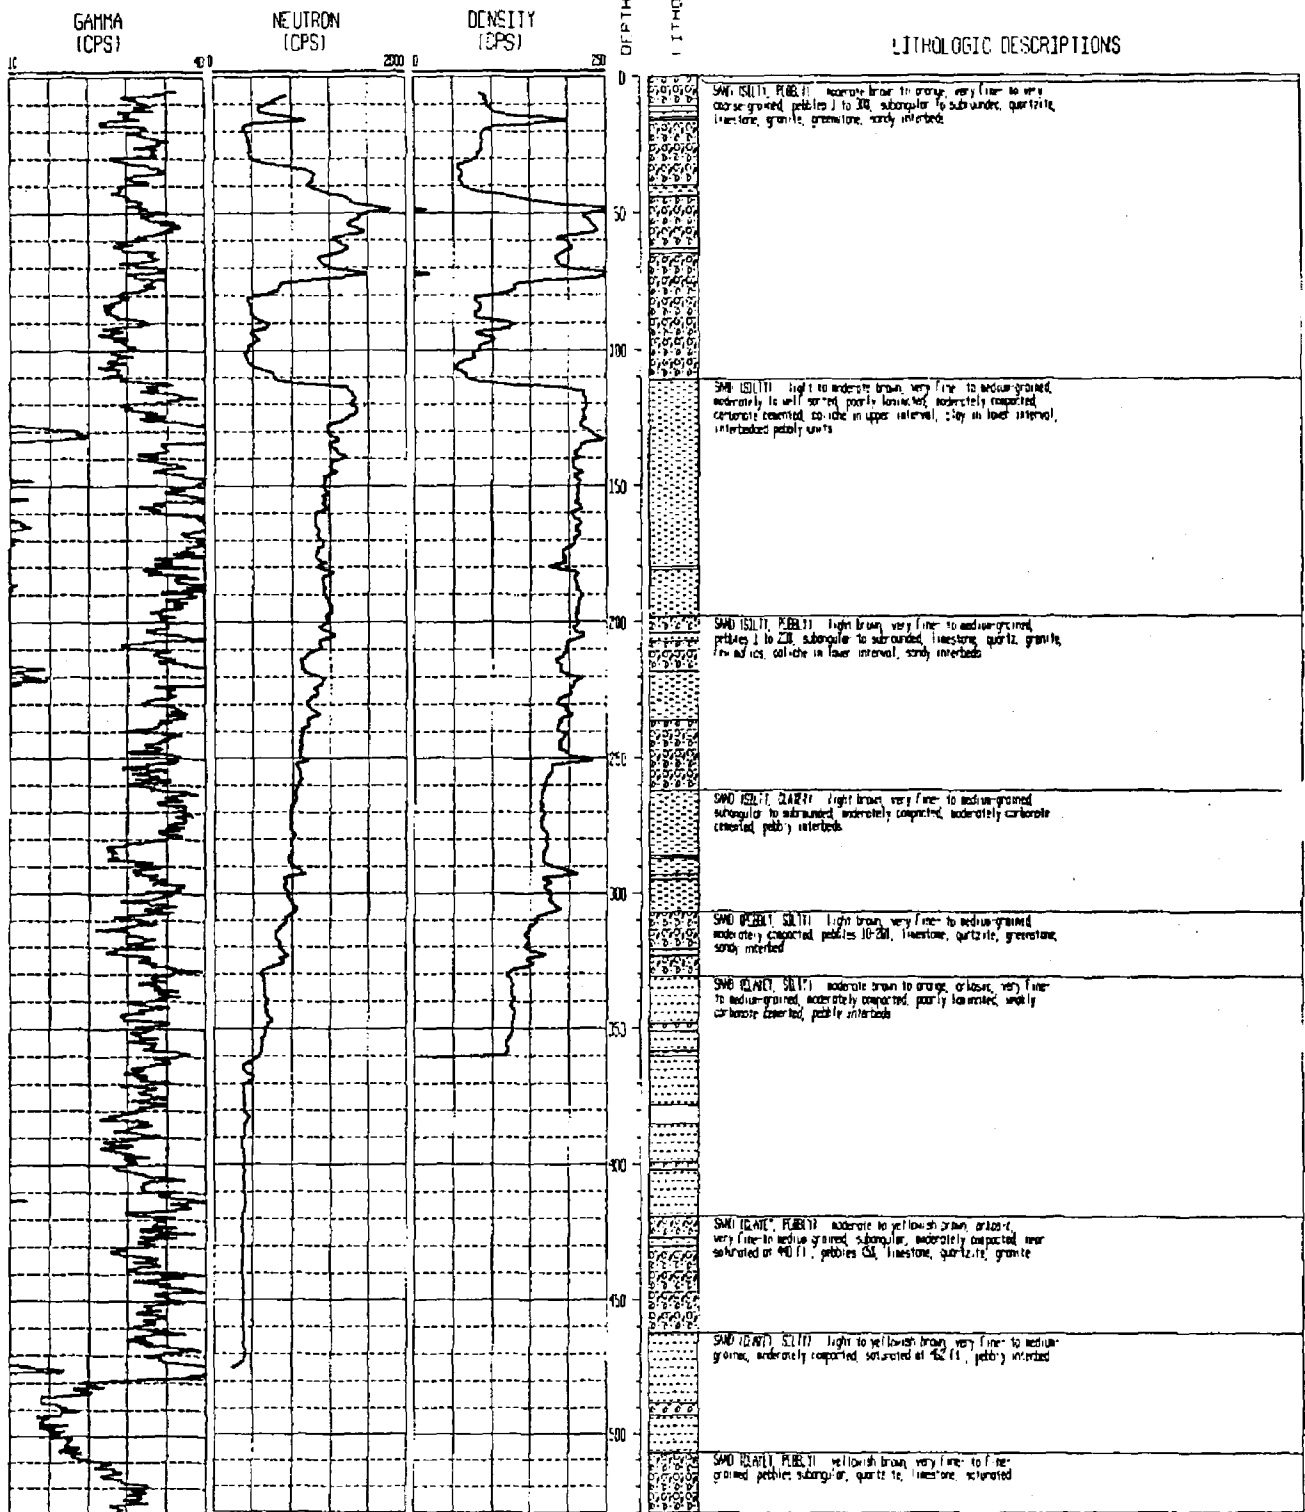

Figure 2-2. LWDS-MW2 Geophysical and Lithologic Log

over time. Below 490 ft, the grain size and K_{sat} increases slightly, possibly suggesting a new sequence. The alluvial fan package in LWDS-MW2 appears similar. Below approximately 480 ft, the GR readings diminish, suggesting the same coarsening seen below 490 ft in LWDS-MW1.

Petrographic analysis was performed with seven samples collected from LWDS-MW1. The samples were collected at selected points from archived core to represent the different layers defined in lithologic and geophysical logs. This analysis showed that mineralogy plays no significant role in the vertical variation in K_{sat} . The general decrease in K_{sat} downward is the result of a decrease in average grain size.

2.5 Hydrogeology

The Rio Grande, located 8 mi to the west, flows in a southerly direction and is the primary surface drainage feature in the Albuquerque-Belen basin. In the basin, the ground-water system is controlled by the Rio Grande and its flood plain, tributary inflow, mountain front runoff, and recharge.

The principal aquifer in the area occurs in the unconsolidated and semiconsolidated sands, gravels, silts, and clays of the Santa Fe Group Formation. The aquifer is generally unconfined, although semiconfined conditions may exist locally because of discontinuous, lenticular silt and clay-rich deposits.

Beneath Kirtland Air Force Base (KAFB), the regional aquifer generally flows toward the Rio Grande at an average gradient of approximately 10 ft/mi; however, local perturbations in the water table are caused by municipal wells as well as lithologic and structural heterogeneity. Before extensive development of the regional aquifer by the City of Albuquerque and KAFB, the predominant ground-water flow direction in the SNL/KAFB area was west-southwest (Bjorklund and Maxwell, 1961); however, municipal pumping by the City of Albuquerque and KAFB has substantially affected the natural ground-water flow regime (Reeder et al., 1967; Kues, 1987). The KAFB production wells have a substantial effect on the hydraulic gradient in the area, creating a cone of depression in the potentiometric surface in the northern portion of KAFB. USGS projections indicate that, by the end of the century, the water table in the Albuquerque area will drop an estimated 30 to 50 ft from 1989 levels (Reeder et al., 1967).

The primary source of ground water in the LWDS area is found primarily in the unconsolidated and semiconsolidated sedimentary deposits of the basin-fill aquifer. A relatively thick unsaturated zone of approximately 460 ft overlies this aquifer. The basin-fill aquifer underlying the LWDS site is recharged primarily by inflow from the mountain areas to the east. Recharge resulting from direct infiltration of precipitation is minor due to the high evaporation, low precipitation rates, and an extensive vadose zone.

3.0 DATA EVALUATION

Data collected during the LWDS investigation were evaluated several ways. Constituents of concern (COCs) are those contaminants that have been identified as possibly being released at a site. Analytical data were examined to determine whether each COC is actually present at the site as a contaminant. This involved a statistical comparison to background coupled with an examination of the spatial distribution of the constituent. Initially, a constituent's concentrations were compared to natural background using EPA-approved methods, as described in Section 3.2.4. Any COC failing the statistical comparison to background (i.e., could not be proven to be within background with 95 percent confidence) was further examined for spatial distribution. Contamination at the LWDS was proven to have a strong spatial correlation to the discharge points in the drainfield and impoundments. COCs that failed the statistical comparison to background and showed a strong spatial correlation were identified as contaminants.

After a constituent is identified as a contaminant, the sample population is compared to EPA action levels and, in most cases, studied in a detailed transport and risk assessment. A SNL/NM-developed computer program, Probabilistic Risk Evaluation and Characterization Investigation System (*Précis*) (Knowlton, 1994), analyzed all contaminants for a particular site (organic compounds, radionuclides, and RCRA metals). The following sections describe this process in greater detail.

3.1 Summary of Quality Assurance/Quality Control Activities

All field activities performed at the LWDS during the implementation of the LWDS RFI work plan (SNL, 1994a) followed strict Quality Assurance/Quality Control (QA/QC) protocols. These protocols in part comprise the collection of the appropriate field QC samples, including equipment blanks, method blanks, duplicate samples, matrix and matrix spike duplicate samples, and trip blanks. QA/QC samples accounted for no less than 5 percent of all samples collected for the RFI investigation.

The QA/QC samples proved to be invaluable during the evaluation of the analytical results. This was particularly germane when reviewing the analytical data for volatile organic compounds (VOCs). Throughout the investigation, common laboratory contaminants including methylene chloride, methyl ethyl ketone (MEK), and acetone

were consistently identified in both the field samples and the QC samples. The consistent presence of these constituents in method blanks and trip blanks suggests that they are attributable to laboratory contamination. Accordingly, low levels of VOC results for these analytes were not considered indicative of organic contamination.

QA/QC procedures employed during this investigation also included verification and validation of the analytical results according to guidelines from AOP94-27 (SNL, 1994b). This verification includes reviewing sample holding times, equipment rinsate, method and trip blank results, and comparing duplicate samples. Some analytical results for individual parameters were out of compliance with respect to one or more of these criteria. Chromium-VI was especially problematic due to the 1-day holding time which could not be met by the off-site laboratory. Table 3-1 identifies those analytes and associated samples evaluated as being out of compliance with programmatic and regulatory requirements. There were relatively few noncompliances, so that the overall integrity of the data package is not expected to be affected.

3.2 Statistical Analysis of Background

As part of the Site-Wide Hydrogeologic Characterization (SWHC) Project, a statistical analysis of the background population was performed. The methodology and analysis results are summarized in the remainder of this section, and are presented in greater detail in the report entitled *Background Concentrations of Constituents of Concern to the Sandia National Laboratories/New Mexico Environmental Restoration Project Phase II: Interim Report*, dated October 1994 (IT, 1994a). The purpose of the SWHC Project investigation was to determine the background concentrations for constituents that occur naturally at SNL/NM, including metals and radionuclides. This investigation included compiling analytical data from samples collected during ER activities at SNL/NM. These data were culled; all samples that were contaminated or had elevated detection limits were removed. The data distribution was then determined, and depending upon the distribution, either a 95-percent upper tolerance limit (UTL) or a nonparametric 95th-percentile value was calculated.

As required in the LWDS RFI work plan, a site-specific background study was also conducted at the LWDS. Sixteen surface-soil background and one duplicate surface-soil sample were collected from an area located northeast of the LWDS surface impoundments. A 50-ft by 50-ft grid was established in this area, situated approximately 1000 ft upwind. Sample collection procedures were identical to those used in the

Table 3-1

surface sampling conducted at the impoundments. The LWDS background data were included in the SWHC Project effort; the LWDS background populations were within SWHC background. However, the SWHC Project-determined background populations were used for data evaluation in this report, rather than the LWDS background data, for several reasons.

- The data sets were much larger;
- The SWHC Project approach was developed to be consistent with current EPA guidance, and the report has been submitted to the EPA; and
- The LWDS background soil samples did not replicate the lithologic range exhibited by the LWDS ER sites.

Advantages of using the site-wide approach included lower cost, greater efficiency, a larger database of individual analyses, and the development of consistent values for the entire facility. Potential disadvantages of the site-wide approach are that it may yield a broader range of values for each COC than is directly pertinent to the LWDS, and it may not be statistically valid if several distinct populations (e.g., from different lithologies) are included in the data set. The latter is addressed by separately checking each data set for multiple populations.

3.2.1 Background Metals in Soil

Seven of the fourteen metals identified in soil samples (barium, beryllium, cadmium, total chromium, copper, nickel, and zinc) were lognormally distributed and therefore analyzed using standard parametric statistical methods consistent with EPA-recommended protocol. No data exist for mercury, tin, or zirconium. Lead, chromium-VI, silver, and total uranium were analyzed using nonparametric methods either because the final working data set possessed a high percentage of nondetect values, or because the distribution was multimodal. Table 3-2 summarizes all critical statistical parameters determined for each constituent. In each case, either a 95-percent UTL (normal or lognormal distribution) or a 95th percentile (nonparametric distribution) was calculated. Several concentration values were rejected a priori for being approximately three to four times greater than the next highest value. Very few additional outliers were identified in the working data sets.

Table 3-2
Summary of Background Concentrations for Metals in Soil
(adapted from IT, 1994a)

Analyte	Original Number of Samples	Number of Detects	Number of Rejected Samples	Distribution Type	Range (mg/kg)	Sample Size	Geometric Mean (mg/kg)	Median (mg/kg)	95% Upper Tolerance Limit (mg/kg)	95th Percentile (mg/kg)

^a Constituents of concern are of unknown distribution type because data are either unusable or nonexistent.
Note: mg/kg = milligrams per kilogram; N/A = Not applicable.

Numerous points representing suspected barium contamination at TA-II were deleted from the overall barium data set, despite the fact that they were not determined to be outliers. This action was justified because barium disposal occurred at the site and the probability plot indicated the presence of two distinct populations. Moreover, an independent statistical background study (IT, 1993) concluded that the observed second population of barium is likely due to anthropogenic activities.

Metal concentration ranges were similar for surface and subsurface data; however, surface-sampling coverage was generally better, resulting in a higher range of values. Better coverage results in a greater observed data range because of the approximately lognormal distribution of the metals; however, total chromium has a higher median at the surface, whereas the other metals for which data are now available (barium, beryllium, cadmium, copper, lead, nickel, total uranium, silver, and zinc) have higher values in the subsurface. With the exception of zinc, the differences between median values for the surface and the subsurface data are minor. Furthermore, the observed variability in the data may be attributable to grain-size differences of the individual samples.

3.2.2 Background Radionuclides in Soil

Eleven of the nineteen naturally-occurring radionuclides (bismuth-212, bismuth-214, cesium-137, cobalt-60, lead-210, radium-224, radium-228, strontium-90, uranium-234, uranium-235, and uranium-238) were analyzed using nonparametric methods because they are either multimodally distributed or have too few detects. Six of the remaining eight radionuclides are either approximately normally distributed (potassium-40) or approximately lognormally distributed (lead-212, lead-214, radium-226, thorium-232, and thorium-234) and were analyzed using standard parametric statistical methods. No background data are available for radon or tritium.

Table 3-3 summarizes all critical statistical parameters determined for each radionuclide COC. In each case, either a 95-percent UTL (normal or lognormal distribution) or a 95th percentile (nonparametric distribution) was calculated. Whereas a few points were rejected a priori, few additional outliers were identified in any of the radionuclide data sets. TA-V consistently has a greater observed range and higher median values for radionuclides than do the other areas. Some high values for cesium-137 in soil collected from TA-V were identified on the distribution plots and were subsequently rejected from the overall data set as suspected contamination.

^a Constituents of concern are of unknown distribution type because data are either unusable or nonexistent.

^b These constituents are not listed as constituents of concern in Table A-1 of Appendix A for this media.

Note: pCi/g = picocuries per gram; N/A = Not applicable.

Several COCs are part of the naturally-occurring uranium-decay series. Because total uranium (Section 3.2.1) and its isotopes are apparently bimodally distributed, the daughter products might also be bimodally distributed. Some COCs show bimodal distribution; however, in a few cases (lead-212, lead-214, radium-226, thorium-232, and thorium-234) the use of standard statistical methods showed approximately lognormally distributed COCs. Except for potassium-40, most of the radionuclides are closer to lognormal than normal distribution type as evidenced by the probability plots.

Several radionuclides showed a broader range of values at the surface than in the subsurface. The reason for this difference is twofold: (1) there were more samples collected for the surface data set, so a greater total number of high values would be expected from the lognormal distribution seen for some of the COCs; and (2) several of the COCs that have been deposited as atmospheric fallout from global nuclear weapons testing are readily adsorbed onto soil and may not have yet reached the subsurface. In that event, however, those COCs associated with atmospheric fallout should be evenly distributed across SNL/NM as well as off-site. For some COCs (e.g., cesium-137 and potassium-40) no significant difference is observed between off-site and on-site localities and/or between on-site localities.

3.2.3 Metals and Nitrates in Ground Water

Background analyses for ground water were performed on a regional basis, rather than by individual area. Due to insufficient data, no statistical analysis was performed with respect to depth.

Of the 14 COCs assessed for ground water, only barium and nitrate had a sufficient number of detects to apply standard statistical methods to characterize the distributions. Where possible, either a UTL (lognormal distribution) or a 95th percentile (nonparametric distribution) was calculated and is tentatively proposed as the background value for the appropriate regions. Table 3-4 summarizes the geometric means, medians, ranges, sample sizes, and UTLs or 95th percentiles. Although most COCs in ground water appear to be approximately lognormally distributed, nonparametric analyses were required for cadmium, total chromium, and lead because of the high proportion of nondetect values. Sufficient data are available for barium, total chromium, and lead to calculate a 95th percentile that is above the stated detection limit of the analyses. Cadmium, nickel, and silver have sufficient data to confirm that the geometric means, medians, and the 95th percentiles are below the detection

Table 3-4

limits of analyses for the entire sampling area. Sufficient data are currently unavailable to determine background values for beryllium, chromium-VI, copper, mercury, tin, zinc, and zirconium; however, sufficient data exist to calculate a regional UTL for both barium and nitrate plus nitrite.

3.2.4 Methodology for the Statistical Comparison of Site-Sampling Results to Background

Several EPA-approved statistical tests were used to compare soil analytical data to background levels. The following sections describe these tests and list the relative strengths of each.

3.2.4.1 *Wilcoxon Rank Sum Test*

The Wilcoxon Rank Sum (WRS) test is performed by ordering all observations from background and the potentially contaminated site according to their magnitude and then assigning a rank from lowest to highest. The ranks in the potentially contaminated area are summed and compared to a table of critical values to determine whether the site is contaminated.

The WRS test is a nonparametric test more powerful than the Quantile test (described below) in determining whether the potentially contaminated area has concentrations uniformly higher than background (EPA, 1992). However, the WRS test allows for fewer less-than measurements than the Quantile test. As a general rule, the WRS test should be avoided if more than 40 percent of the measurements in the potentially contaminated area or background are nondetects. All soil analytical data were subjected to the WRS test in this analysis, although the test power was greatly reduced when the nondetect percent was greater than 40.

3.2.4.2 *Quantile Test*

The Quantile test is performed by separating background data and individual site data. The data are then ordered from highest to lowest. The number of background and individual site data points are calculated. The number of data points for background and the selected potentially contaminated site is then compared to a table that identifies how many of the highest measurements must come from the potentially contaminated site versus background to indicate contamination.

The Quantile test is a nonparametric test that has more power than the WRS test to detect when only a small portion of the remediated site has not been completely cleaned up. Also, the Quantile test can be used even when a fairly large proportion of the measurements is below the limit of detection (EPA, 1992).

3.2.4.3 Hot-Measurement Comparison (Upper Tolerance Limit) Calculation

The hot-measurement comparison consists of comparing each measurement from the potentially contaminated area with an upper-limit concentration value. This upper-limit concentration value is such that any measurement from the potentially contaminated area that is equal to or greater than this value indicates an area of relatively high concentrations that must be further investigated (EPA, 1992). Concentrations exceeding the upper-limit value may indicate inappropriate sample collection, handling, or analysis procedures, or actual contamination.

The upper-limit concentration value was calculated in the SWHC Project background study based on the 95th percentile for nonparametric data and the 95th UTL for parametric data.

3.2.4.4 Kolmogorov-Smirnov Test

The Kolmogorov-Smirnov (KS) test calls for two independent samples and tests the null hypothesis that the two samples come from identical distributions. This is achieved through the calculation and comparison of the cumulative distribution functions for each sample (Steel and Torrie, 1980). The maximum numerical difference between the two calculated values is compared to tables of critical values. If the data do not support the null hypothesis, it is concluded that the two samples are from different populations. The test is also sensitive to differences in variance, since it is a test of the equality of distributions rather than of specific parameters.

The KS test is a nonparametric test that can be used to evaluate the fit of any distribution. In general, the KS test is considered more powerful than alternative goodness-of-fit chi-square tests. The three general limitations are (1) the method is computationally complex; (2) it requires large sample sizes for greatest power (i.e., 50 or more); and (3) the parameters of the hypothesized distribution (e.g., mean and variance

of a normal distribution) are assumed to be known (Gibbons, 1994). Lilliefors (1967, 1969) generalized the test to the case of a normal or lognormal distribution with unknown mean and variance, although the method is still computationally complex and requires large samples.

The KS test was applied to soil data from all LWDS sites, but the test results are not further discussed in Section 4.0. The test analyzes distributions and is comparatively less powerful if the sampled population is not grossly contaminated.

3.2.4.5 Student's T-Test

The t-test is a parametric test that compares the means of two samples. To use the t-test statistic, both sampled populations must be approximately normally (or lognormally) distributed with approximately equal population variances, and the random samples must be selected independently of each other.

The equations and methodology for applying the t-test are explained in most statistics books, including McClave and Dietrich (1982) and Mendenhall (1975).

3.3 Resource Conservation and Recovery Act Action Levels

Action levels are concentrations of various parameters in soil, water, or air above which a corrective measure study for the facility could be warranted. These levels are determined to be indicators to protect human health and the environment. For air, surface soils, ground water, and surface water, generic action levels were estimated using assumptions outlined in RCRA (40 CFR 264) proposed Subpart S. The use of action levels allows a quick evaluation of the risk associated with the sampled concentrations of contaminants. In the case of the LWDS holding tanks, this evaluation indicated that the site should be proposed for No Further Action. For the other two LWDS ER sites, the comparison to proposed Subpart S action levels was inconclusive and a site-specific risk assessment was performed.

3.4 Contaminant Fate and Transport/Risk Assessment

All contaminants at the surface impoundments and drainfield were evaluated in a site-specific risk assessment. After a constituent was determined to be anthropogenic, the *entire* sampled population was used in the site-specific risk assessment, including concentrations within natural background levels.

The computer model developed by SNL/NM, *Précis*, was used (Knowlton, 1994). The basic risk assessment methodology defined by the EPA (1989) has been modified to include a quantitative uncertainty analysis technique. Initially, the SNL/NM risk assessment employs relatively simple process models to describe transport processes and conservative distributions of input parameters. If more detailed site-specific analysis is required, the preliminary risk assessment may be modified to include more rigorous analytical or numerical process models to describe transport processes. The probabilistic risk assessment methodology is ideal for quantitatively assessing uncertainty. Site-specific sections (Sections 4.2 and 4.3) list the risk assessment results, and Annexes I and II contain further details relating to future land use and exposure unit definitions.

3.5 Development of Conclusions and Recommendations

Ultimately, data for each site were evaluated to determine the adequacy of site characterization and to assess the risk each site poses to human health and the environment. This evaluation addressed the need for any potential future actions and the site disposition.

Site 4 consists of the two surface impoundments (Impoundments 1 and 2), constructed in June 1967 and June 1970, after the collapse of the LWDS drainfield. These impoundments are referred to in the RFA as SWMUs 18 and 19 (EPA, 1987). The two impoundments are located approximately 1000 ft northwest of the LWDS holding tanks and 400 ft north of the TA-III gate (Figure 4-12).

Impoundment 1, the eastern impoundment, covers 8100 ft² and measures 65 ft by 125 ft by 12 ft deep. Impoundment 2 covers approximately 9400 ft² and measures 102 ft by 92 ft by 20 ft deep. Neither impoundment is lined. Impoundments 1 and 2 were used for the disposal of primary coolant water from the SERF, and the potentially contaminated waste water from experiments and operations in the SERF buildings. In addition, waste oil and resin beads were disposed of in the surface impoundments on at least one occasion. The volume and radionuclide content of the discharges to Impoundments 1 and 2 between 1967 and 1971 were monitored and recorded. During those 5 years, approximately 12 million gal of waste water containing approximately 14 Ci of measured radioactivity were discharged. It is assumed that the majority of these radionuclides were deposited in Impoundment 1, because Impoundment 2 was installed later, near the end of the time in which radioactive discharges occurred. The short half-life activation products have decayed and potential residual contamination consists of fission products, other radionuclides, and laboratory solvents.

The last discharge of radioactive waste water from reactor operations occurred in April 1970. SERF waste-water discharges to the impoundments were tracked and recorded until July 1971, when the Atomic Energy Commission (AEC) relaxed this reporting requirement because the reactor was no longer in operation. Since that time, however,

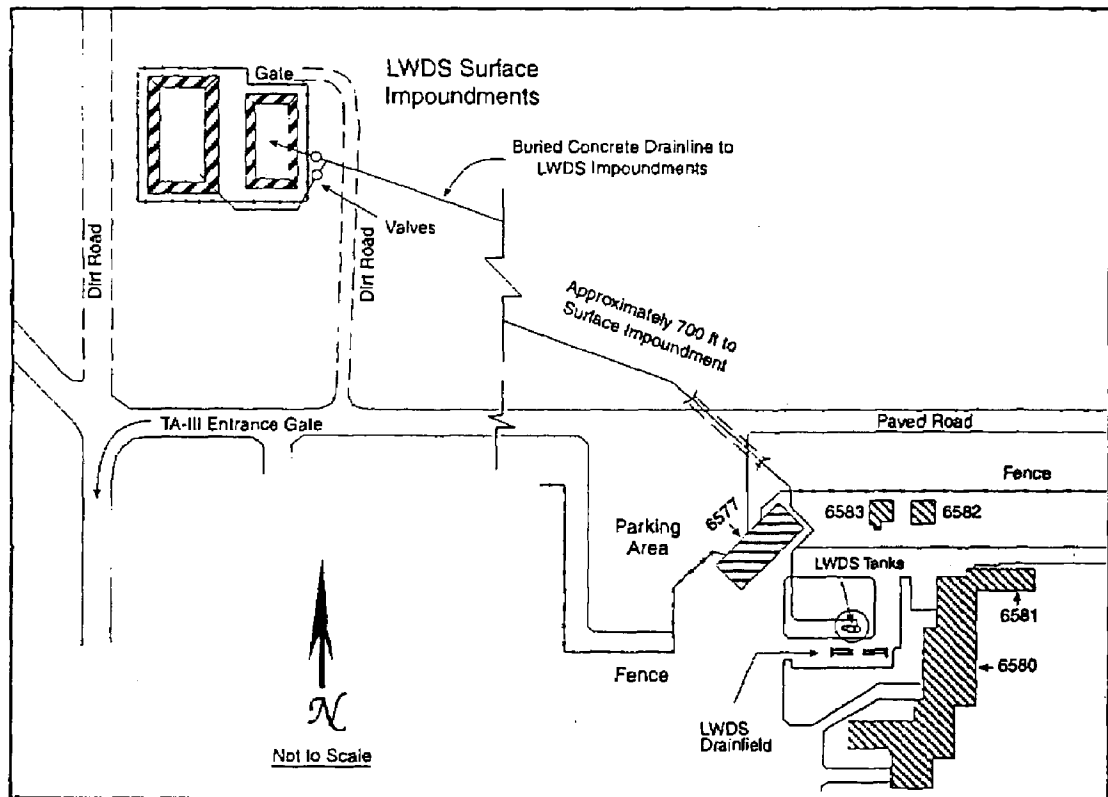

Figure 4-12. Liquid Waste Disposal System Site Map

the impoundments have continued to receive intermittent waste-water discharges consisting of unmonitored, reportedly uncontaminated process-chilled water and waste fluids discharged to the LWDS through sinks and floor drains in the HCF. These discharges were ordered to be stopped by the DOE in September 1992 and the impoundments are now inactive.

Previous Investigations

Water, soil, and sludge samples were collected at both impoundments from 1971 through 1984. This sampling was sporadic and poorly documented but, based on common practices at that time, it is believed that all of the samples were collected from the lagoon surfaces. At that time, cobalt-60, cesium-137, manganese-54, and some alpha and beta activity were identified at low levels.

In September 1983, one or both of the impoundments was used as a "decontamination catch bin" by the U.S. Air Force (USAF) for unknown purposes (SNL, 1983). Soil and

sludge samples collected 1 year later, in September 1984, from Impoundment 1 contained 24.6 parts per million (ppm) PCBs (SNL, 1984). A direct connection between this use of the impoundments and the level of PCBs found in the soil in the 1984 sampling cannot be verified due to the absence of USAF disposal information. Analyses were not conducted at that time for compounds other than PCBs. The sample was probably taken from the surface soil; PCBs are generally strongly sorbing chemicals.

4.3.1 Contamination Sources

The principal use of the LWDS surface impoundments as part of the LWDS network was well defined. Liquid waste from TA-V was conveyed to the impoundments where evaporation and infiltration occurred. Accordingly, the source of impoundment contamination is well understood as being the liquid waste from TA-V. The USAF activities at the impoundments are undocumented. Accordingly, additional surface sampling that accounts for surface discharges to the impoundments was also performed.

4.3.2 Field Investigation

Field investigations performed at the LWDS surface impoundments were designed to evaluate the horizontal and vertical extent of contamination. Investigation activities included: a surface inspection/walk-over, radiation and organic vapor surveys, surface sampling, a geophysical survey, nine boreholes, and installing one ground-water monitor well. These field investigations are described in the remainder of this subsection.

Preliminary Radiation Survey and Site Screening

A walk-over radiation survey and site screening was performed prior to any intrusive activities at the LWDS surface impoundments. The impoundments and surrounding region were carefully studied for any indications of potential contamination, such as soil discoloration or distressed vegetation. No soil discoloration or distressed vegetation was found; however, resin beads were dispersed in the soil directly beneath the surface of the Impoundment 1 drainline outfall. These resin beads probably resulted from backflushing of the ion-exchange resin beds, the major discharge activity of the SERF.

Surveys were conducted for detectable organic vapors and radioactive hotspots concurrent with the walk-over inspection. A slow scan of the entire fenced region inside and surrounding the impoundments was conducted using a micro-R-meter at a distance

of approximately 1 m above the ground and a 2-in. sodium iodide (NaI) gamma scintillation detector at ground level. An organic vapor analyzer (OVA) flame ionization detector (FID) was used to measure organic vapors.

No organic vapors were detected, and gross gamma-radiation levels were well within the normal background except for the area immediately beneath the Impoundment 1 drainline outfall (the same region that contains resin beads). The readings in this area were highest at the outfall and decreased with distance from the outfall. The readings were indistinguishable from background levels at approximately 5 to 7 yd from the outfall. The highest readings detected with the micro-R-meter were approximately 1.5 times the background levels and, with the NaI gamma scintillation detector, were approximately 3 times the background levels.

Surface Soil Sampling

The initial investigation at the LWDS surface impoundments involved collecting surface soil samples at grid locations within and around the impoundments. Licensed surveyors superimposed (and recorded) a 10-yd by 10-yd sampling grid over the 60-yd by 80-yd area. Samples were collected from the center of each 10-yd by 10-yd square. Judgmental samples were collected at the drainage outfalls on the surface and at a depth of 1.5 ft. A total of 80 soil samples was collected during this investigation. Figure 4-13 shows the locations of the surface soil samples and the overlying sample grid. A vegetation sample was collected and analyzed for possible uptake of tritium.

All soil samples were collected with a stainless-steel trowel that was decontaminated after collecting each sample. Prior to sampling at a given location, approximately 2 in. of sediment was scraped away to ensure that a representative sample was obtained. Appendix B describes the methods used for sample analyses.

Controlled Source Audiofrequency Magnetotelluric Investigation

In September 1992, GeoPacific Research and Exploration conducted a geophysical survey at the LWDS surface impoundments using Controlled Source Audiofrequency Magnetotellurics (CSAMT). This section summarizes the results of the survey; more information is available from the survey report (GeoPacific Research and Exploration, 1992). CSAMT is a non-invasive, remote-sensing technique deployed at ground-surface to provide subsurface, structural information through measurement of variations in the electrical resistivity. The survey was designed to assess the nature of subsurface

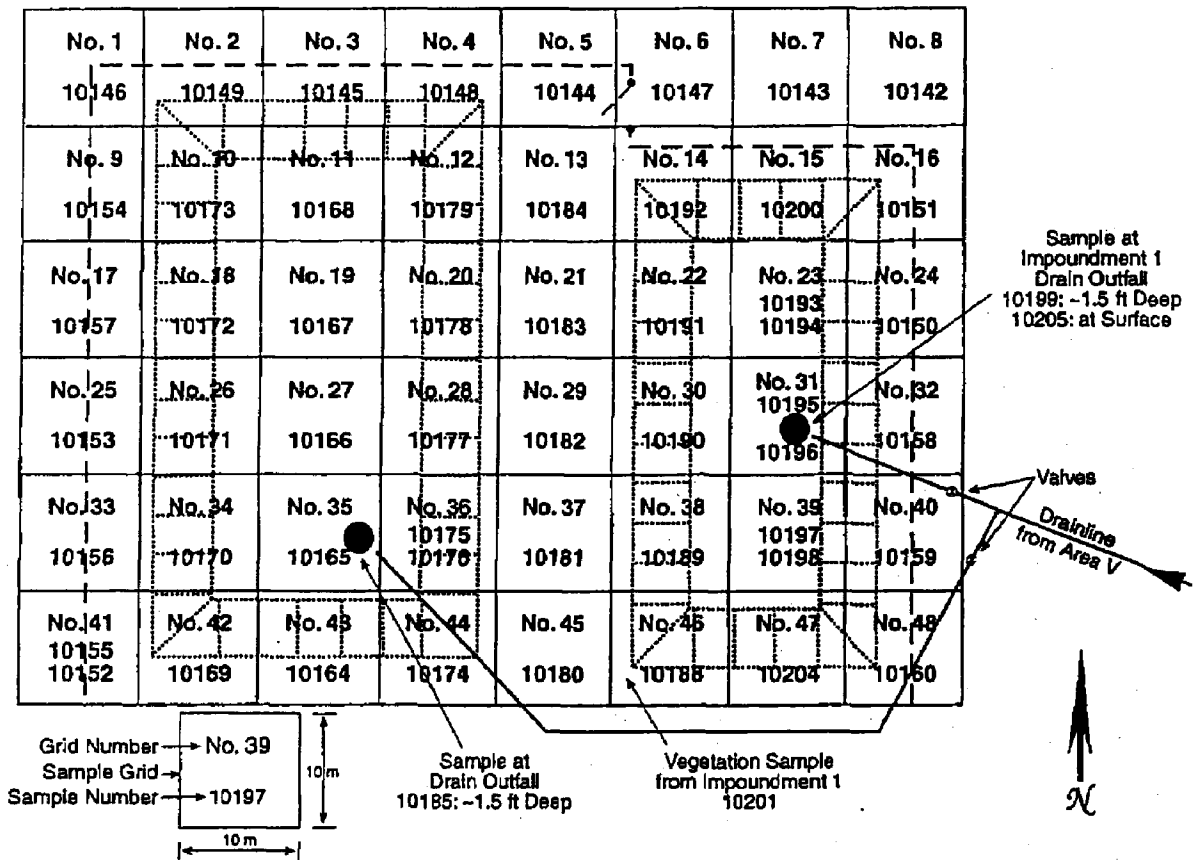

Figure 4-13. LWDS Surface Impoundments Surface Sample Location Map

features which may have resulted from infiltration of waste water into the surrounding subsurface environment. This was accomplished by determining the overall background electrical resistivity structure of the area and locating electrical resistivity anomalies expected to be associated with a water-containment sump.

The survey included instrument deployment and vector data acquisition at 100 surface sites. Sensor locations were chosen to help determine the lateral and vertical extent of migration of fluids from the LWDS surface impoundments. The CSAMT survey delineated a 100-yd by 200-yd area north and west of the LWDS surface impoundments

with significantly elevated electrical conductivity within approximately the upper 180 ft bgl. Figure 4-14 shows the location of the survey instruments and the area of elevated conductivity. Such an anomaly could be produced by locally increased dissolved contaminants, increased fluid saturation, increased local permeability, or a combination of these factors.

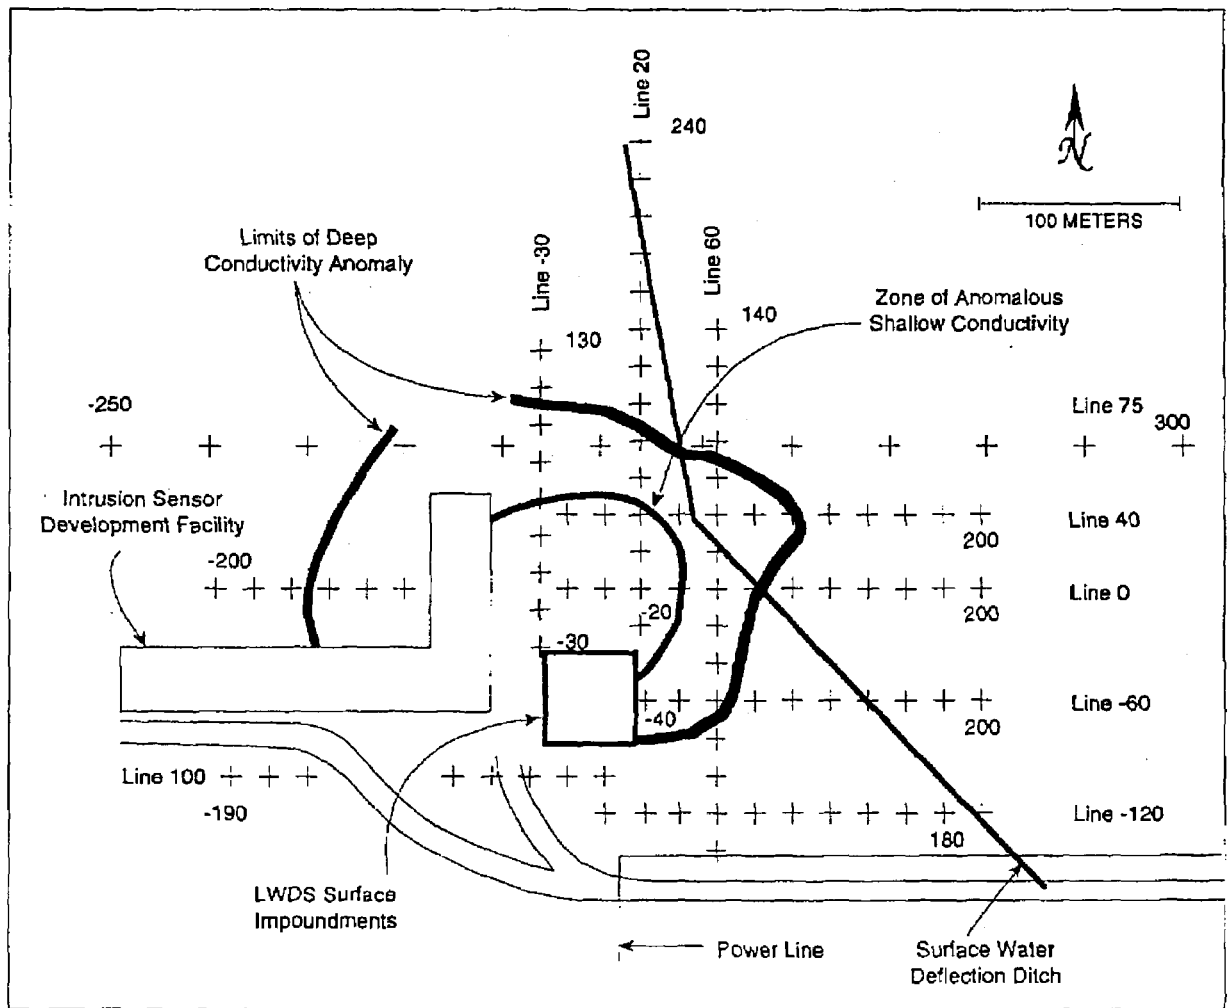

Figure 4-14. CSMAT Site Locations and Limits of the Conductivity Anomaly

CSAMT data collected along the southern edge of the sump show only limited resistivity variations and suggest that water from the sump has not migrated substantially to the south; however, it should be noted that buildings and roads limit the area available for data collection to the south, and there is a high level of cultural noise (i.e., interference from electrical sources in the area) on this side of the impoundments. Thus, conclusions about the resistivity structure to the south are more tentative than those regarding the resistivity structure to the north.

The background electrical resistivity structure away from the conducting anomaly north of the sump consists basically of two discrete layers. The shallow, high-resistivity layer has a vertical thickness of approximately 180 ft and is thought to be above the depth of fluid saturation. Below 180 ft, there is a substantial change in the electrical resistivity, which may indicate a lower soil moisture level. Physical conditions found in the impoundment subsurface investigations do not support the interpretations of the CSAMT survey, as discussed later in this section.

Boreholes

Nine boreholes have been drilled at the LWDS surface impoundments. Figure 4-15 shows the locations of these boreholes. Table 4-5 lists the numbers and depths of the boreholes drilled as part of the surface impoundment investigation.

Boreholes 1 through 5 were completed in August 1992. These perimeter boreholes were installed first and the boreholes planned for inside the impoundments were delayed by mixed waste problems (described in Section 4.1.2). As previously stated, continuous core was collected at each location. Soil samples were then collected from the core at 5-ft intervals and submitted to the analytical laboratory for analysis (as described in Appendix B). Section 4.3.3 summarizes the analysis results.

DOE approval to generate mixed waste was obtained in March 1994 and Boreholes 9 and 10 were completed in the impoundments. The field screening and analytical programs matched those used for previous boreholes (Appendices A and B). Section 4.3.3 also summarizes the analysis results.

Following an EPA directive, a second borehole was installed in each impoundment. Based on the results of the first set of boreholes, mixed waste generation was

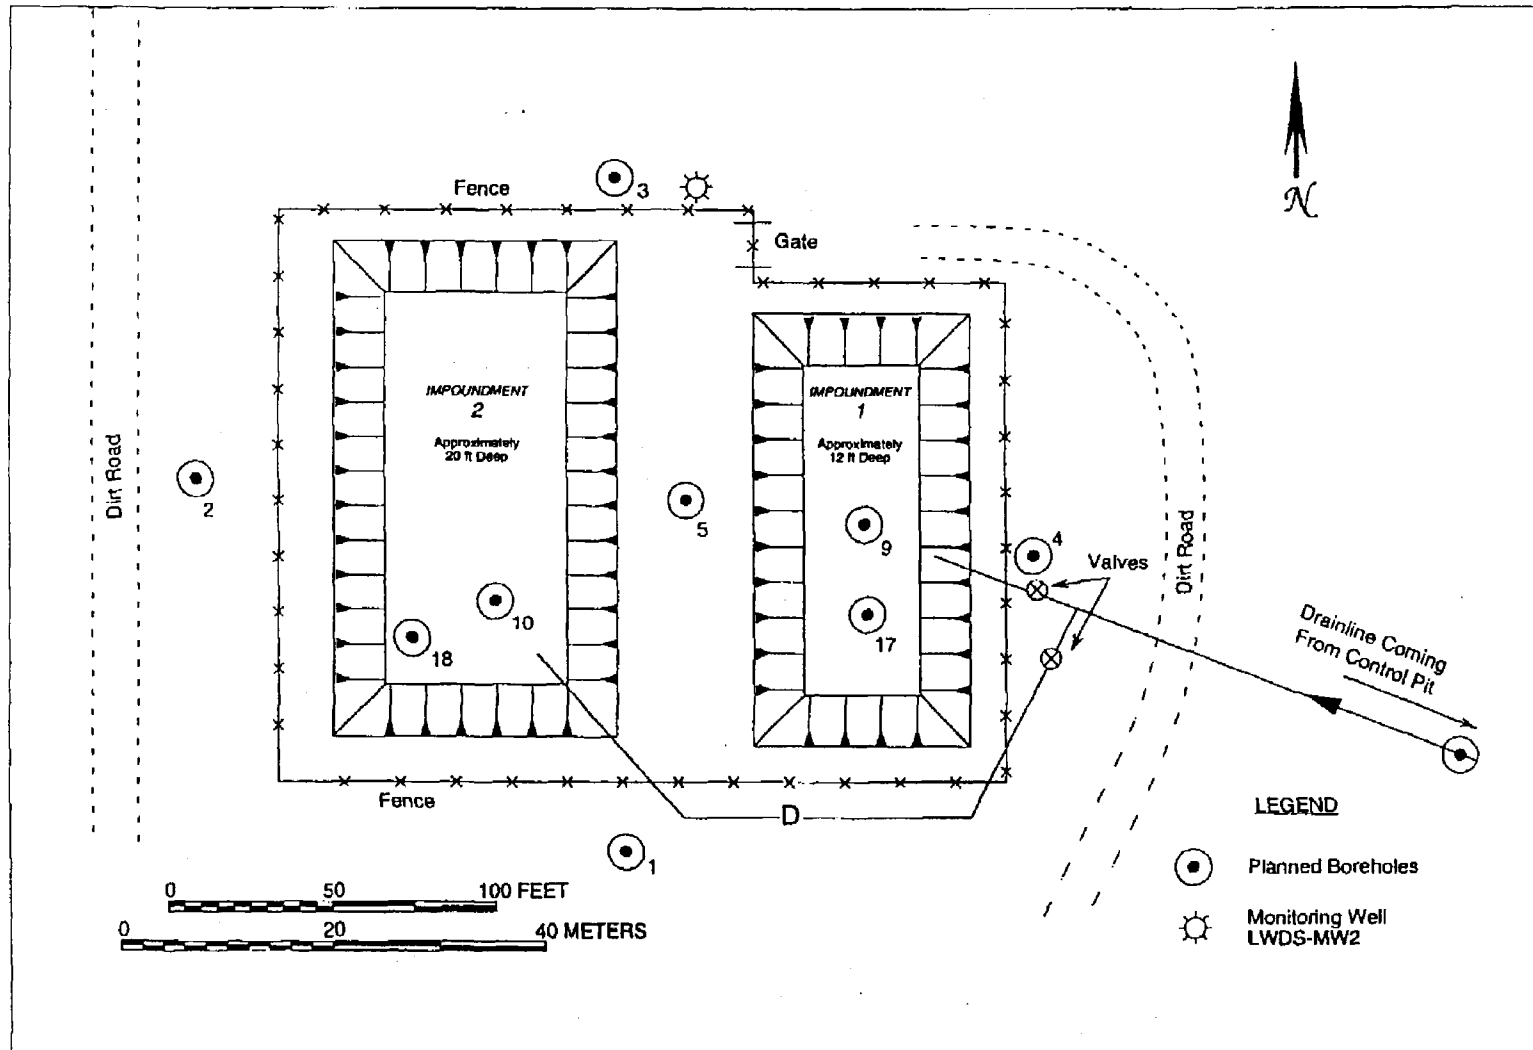

Figure 4-15. LWDS Surface Impoundments Borehole Locations

Table 4-5
Total Depths of Boreholes Drilled at the LWDS Surface Impoundments

Borehole Number	Total Depth (ft bgl)

BH-10	30
BH-17	60
BH-18	30
Note: ft bgl = feet below ground level.	

considered unlikely and a *Failing F-10* hollow-stem auger drill rig was used. During this investigation, soil samples were collected with a split-spoon sampler at 5-ft intervals.

Monitor Well Installation

In September 1992, monitor well LWDS-MW2 was drilled north of the LWDS surface impoundments. The borehole was drilled with a combination of rotasonic, air rotary, and cable tool methods to a total depth of 531 ft bgl; it was completed in October 1992. The monitor well is constructed of 4.5-in.-diameter Schedule 40 stainless-steel screen and PVC riser. The screened interval extends from 506 to 526 ft bgl. Well development was performed in May 1993.

Ground-Water Sampling

Quarterly ground-water samples were collected from LWDS-MW2 following sampling procedures as summarized in the *LWDS Ground-Water Monitoring Project Site Sampling Plan* (IT, 1994c).

4.3.3 Nature and Extent of Contamination

A review of the analytical results with respect to background levels identified several metals and radiological contaminants. Most of the contamination in the impoundments was concentrated under the drainline outfalls and contamination was higher in Impoundment 1 than in Impoundment 2. PCBs also were identified in the southwest corner of Impoundment 2. The remainder of this subsection presents further contaminant details.

Metals

The metal-analytical results were evaluated as described in Section 3.2. Table 4-6 summarizes this evaluation. A total of seven metals were identified as surface impoundment contaminants. In general, metal contamination is limited to surface and near-surface samples, and is concentrated beneath the drainline outfalls. No contamination was detected at depths greater than 5 ft. Figures 4-16 through 4-22 show the surface contaminant contours developed for these metals.

Chromium-VI contaminant contours are not shown. Three chromium-VI results were slightly above the detection limit. The spatial analysis did not correspond with the other contaminants or known discharge points but based on a zero background level, the results indicated contamination and were included in the risk assessment. A brief review of Table 4-6 will show the validity of the spatial analysis. In many cases, the maximum measured concentration was less than background UTL. However, a spatial analysis showing a consistent constituent grouping would indicate anthropogenic contribution.

The opposite case was also true. A maximum concentration exceeding the background UTL did not necessarily indicate contamination. Rather, the spatial and statistical analysis was used to identify an anomalous high value.

Beryllium was problematic in that an especially high value (4.9 mg/kg) was measured in grid 48 (Figure 4-13). The anomalous value caused several statistical tests to fail for beryllium yet no pervasive problem was apparent. Six additional samples were taken (five soil and one duplicate) in the immediate vicinity of the high analysis result on May 23, 1995. These samples were analyzed off-site. The sample results ranged from

Table 4-6
Statistical Comparison of Site 4 to Background

Parameter	Distribution	T- Test		Wilcoxon	Quantile	Upper Tolerance Limit (UTL)	Maximum Concentration	Spatial	Site 4 Contaminant
		= Variance	≠ Variance						
Barium	Lognormal	Fail	Fail	Pass	Pass	398.1 (mg/kg)	849 (mg/kg)	Fail	Yes
Beryllium	Lognormal	Fail	Fail	Fail	Pass	.79 (mg/kg)	4.9 (mg/kg)	Pass	No

0.35 to 1.3 mg/kg, which are typical values for this region. The new samples were not used in the statistical analysis but they show the original value as anomalous.

Radionuclides

Table 4-6 also summarizes the radionuclide analysis evaluation. Radionuclides well above background were only identified in samples collected during the surface sampling investigation. The surface contamination measured in this sampling event followed expected patterns. The highest levels of contamination were directly under the Impoundment 1 drainline outfall, whereas contamination is barely detectable in Impoundment 2. This pattern was expected because Impoundment 2 was constructed toward the end of the time period in which known radioactive contaminants were discharged. The total amount of contamination was fairly low; cobalt-60, cesium-137, tritium, and uranium-235 were the only detected anthropogenic radionuclides. Figures 4-23 through 4-25 show the surface contaminant concentration contours developed for cobalt-60, cesium-137, and uranium-235. Surface contaminant contours are not provided for tritium which had only trace levels barely detectable at 5 ft bgl in Boreholes 9 and 10.

(in picocuries per gram [pCi/g])

Figure 4-26. Surface Contaminant Contour Plots of Polychlorinated Biphenyls (PCBs)
at Impoundment 2

Tritium was not detected in the vegetation sample.

Polychlorinated Biphenyls

The PCBs detected in surface soil do not follow the pattern described previously in that the highest concentrations of PCBs are not in the eastern impoundment beneath the drainline outfalls. PCB concentrations were not expected from TA-V activities and were not found near any drainlines; however, PCBs were detected in three soil samples collected from the southern end of the western impoundment (Impoundment 2). Figure 4-26 shows the surface contaminant concentration contours developed for PCBs in Impoundment 2. This concentration pattern could be explained by an isolated discharge in the southwest corner of Impoundment 2. No PCBs were detected in any soil samples collected from the subsurface. The highest result was 71 ppb, detected in the southwest corner of the western impoundment. This value compares favorably to the 40 CFR 264, proposed Subpart S, soil action level of 10,000 ppb for PCBs.

Ground Water

No contamination has been identified in monitor well LWDS-MW2 since its installation. Water quality analysis results appear to be representative of the regional background.

4.3.4 Risk Assessment

The SNL/NM *Précis* (Version 1.1.3) was used to estimate potential radiation doses, incremental lifetime cancer risks, and the systemic toxic hazard index associated with contaminated soil at the surface impoundments (Knowlton, 1994). All estimates were made according to an industrial land-use scenario. Annex II includes the entire risk assessment documentation.

This risk assessment indicates that external radiation exposure from cobalt-60 is a potential radiation dose to workers. Uranium-235 and tritium detected in some soil samples were not significant contributors to radiation dose. According to the analysis, a worker would have a 51 percent probability of exceeding the 25-mrem/yr radiation dose limit specified in DOE Order 5820.2A (DOE, 1988). The maximum radiation dose was estimated to occur in 1994, but the estimated dose is decreasing with time as a result of the radioactive decay of cobalt-60.

Estimates of incremental lifetime cancer risk from potential exposures to carcinogenic chemicals indicate that a worker in 1994 would have had a 52 percent probability of incurring greater than the 1×10^{-6} cancer risk limit judged acceptable by the EPA (EPA, 1989). This cancer risk was associated primarily with potential ingestion of soil containing cadmium and chromium-VI.

Estimates of systemic toxicity associated with potential exposures to chromium-VI, copper, mercury, nickel, and zinc indicate that the hazard index for a worker at ER Site 4 would be 0.04 or less with 95 percent probability. Thus, the estimated hazard index is far less than the value of 1.0 specified by the EPA (EPA, 1989).

Because sufficient information is not provided to address the potential health risk associated with lead in soil, no risk assessment for lead was made for this report. However, all lead concentrations reported for soil at ER Site 4 are far below the 400-ppm screening level specified by the EPA (EPA, 1994). The highest concentration of lead detected in soil at the LWDS surface impoundments was 72.5 ppm.

4.3.5 Summary and Conclusions

The risk assessment indicates that concentrations of cobalt-60, cadmium, and Chromium-VI may be high enough to require remediation at ER Site 4 (Section 4.3.4). However, the following recommendations are made to support a proposal of No Further Action:

1. Part of site closure activities will include filling the impoundments to grade with native soil. This leveling is required for safety considerations and is not considered a corrective measure. This fill will be a minimum of 6 ft and more than 12 ft thick in most places. This action, although not specifically required for risk reduction, will lower the total risk from carcinogenic chemicals and radionuclides under the industrial land-use scenario, such that estimated cancer risks and radiation doses are far below the applicable limits for the residential land-use scenario at 1×10^{-6} risk.

2. The risk assessment was based on the conservative EPA cancer risk limit of 1×10^{-6} specified in *Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual* (EPA, 1989). Recent EPA guidance provides cancer risk estimates up to 1×10^{-4} that might be acceptable (*Role of the Baseline Risk Assessment in Superfund Remedy Selection Decisions*, OSWER Directive 935,0-30, 1991). This latter guidance states, in part, "Records of Decision for remedial actions taken at sites posing risks within the 10^{-4} to 10^{-6} range must explain why remedial action is warranted." The risk assessment shows that cancer risk from cadmium and chromium-VI is well within the 1×10^{-4} risk limit and No Further Action would be appropriate.

1.0 INTRODUCTION

Sandia National Laboratories/New Mexico (SNL/NM), located in Albuquerque, New Mexico, is committed to the protection of human health and the environment. Because of this commitment, potential risks to human health and the associated action levels were calculated for the constituents of concern (COC) detected in soil samples obtained from the Liquid Waste Disposal System (LWDS), Environmental Restoration (ER) Site 4.

The following analysis involves calculating the potential radiation dose, cancer risk, or toxicity hazard to a worker at the site. This approach addresses uncertainties associated with various site-specific parameters (e.g., soil density and annual precipitation) and the variability of soil-contamination measurements. These calculations provide estimates of potential radiation dose, risk, and hazards and their uncertainties as compared with limits specified by regulations. Sections 3.0 through 5.0 describe this approach.

Annual radiation doses resulting from the radionuclide COCs were estimated using the SNL/NM *Précis* computer program, Version 1.1.3a (SNL/NM 1994a). The results of the radionuclide COC human health risk assessment were compared with the 25 millirem per year (mrem/yr) dose rate, which is the U.S. Department of Energy (DOE) performance objective for limiting a radiation dose to any member of the public (DOE 1988).

Human health effects from potential exposure to nonradioactive COCs were also estimated using *Précis*. The incremental lifetime cancer risk (ICR) was estimated for potential exposures to carcinogenic chemicals. The hazard index (HI) was estimated for potential systemic toxic effects (e.g., kidney damage) resulting from exposure to noncarcinogenic chemicals. These calculated ICR and HI values were compared with values regarded as acceptable by the U.S. Environmental Protection Agency (EPA). The acceptable ICR is 1×10^{-6} ; the acceptable HI is 1.0 (EPA 1989).

2.0 SITE CHARACTERIZATION

2.1 Site Description

The ER Site 4 Liquid Waste Disposal System consists of two unlined surface impoundments used from 1967 to 1971. The impoundments are located outside of Technical Area (TA) 5 and north of the TA-3 fence (Figure 2-1a and 2-1b, SNL/NM 1993). The western impoundment is 100 feet (ft) long by 50 ft wide by 30 ft deep. The eastern impoundment has the same dimensions but is 20 ft deep. These impoundments collected radioactive waste water discharged from the TA-5 holding tanks that received waste from the TA-5 hot cell laboratory and reactor and from the floor drains and sinks in Building 6580.

2.2 Contamination Assessment

Soil samples were obtained from ER Site 4 in October 1994 (SNL/NM 1993). Surface and subsurface samples were analyzed for radioactive and chemical contaminants. Contaminants not detected in any sample were not considered further. Contaminants that were detected above ER Site 4 background concentrations were considered to be COC for the assessment of risks.

Although copper was detected in some of these soil samples, copper is not regulated under Resource Conservation and Recovery Act (RCRA) (Title 40 Code of Federal Regulations Part 261, Appendix VIII [40 CFR 261, Appendix VIII]) except as copper cyanide produced in copper mining operations (40 CFR 261.4). Therefore, copper was not included in this risk assessment.

Appendix A summarizes the COC concentrations in soil at ER Site 4. All of the COC data sets were fitted to determine if the data were normally or lognormally distributed. Several of the COC data sets are heavily censored, such that the distribution type could not be determined. It is commonly found that large and uncensored data sets describing environmental soil contamination are lognormally distributed. Therefore, all of the ER Site 4 data distributions were determined or assumed to be lognormally distributed (Appendix A).

The chromium concentration distribution included a single measured concentration of 97.7 ppm chromium/gram soil, which is above the 99.9th percentile of the lognormal distribution (90.9 ppm chromium/gram soil). This circumstance is consistent with the distribution in which the probability of a concentration measured above 90.9 ppm is 0.1%. An assignment of the 97.7 ppm value to the 99.9th percentile of the distribution is not expected to appreciably affect the small Hazard Index associated with potential exposure to noncarcinogenic chemicals (see Section 5.2).

The distribution of ER Site 4 data sets that could not be shown to be normal or lognormal were assumed to be lognormal (EPA 1992), with the detection limit set equal to 0.1th percentile and the maximum detected value set equal to the 99.9th percentile.

2.3 Constituents of Concern

Four radionuclides, seven metal species, and one polychlorinated biphenyl (PCB) compound were identified as COC in soil at ER Site 4. Except for the PCB aroclor-1260, no other organic chemicals were analyzed above laboratory quantitation limits, and none are considered to be contaminants at the site. Table 2-1 shows the COCs and the statistical distribution information used as input to *Précis*.

Summary of Soil Concentrations for Constituents of Concern at the
SNL/NM ER Site 4 Liquid Waste Disposal System Impoundments**

Contaminant (Unit of measure)	Number of Samples	Soil Concentration				
		Minimum ^a	Maximum	Distribution (Appendix A)	0.01 Percentile	99.9 Percentile
Cesium-137 (pCi/g)	26	0.037	10.1	Lognormal	0.003	81.6
Cobalt-60 (pCi/g)	26	0.033	11	Lognormal	0.002	36.4
Tritium (pCi/g)	30	0.05	0.40	Lognormal	0.015	0.58
Uranium-235 (pCi/g)	26	0.049	3.0		0.015	3.85
Aroclor-1260 (ppb) ^b	24	33	71	Lognormal	33	71
Barium (ppm)	26	54.5	232	Lognormal	0.011	81.6
Cadmium (ppm)	26	0.5	154	Lognormal	0.003	480.2
Chromium(III) (ppm)	26	6.2	97.7	Lognormal	1.92	90.9
Chromium(VI) (ppm)	22	0.1	11.2	Lognormal	0.007	35.2
Lead (ppm) ^c	26	5.8	72.5	c	c	c
Nickel (ppm)	26	4.7	173	Lognormal	0.82	209.0
Zinc (ppm)	26	21	198	Lognormal	6.92	286.1

^aThe minimum reported value in the data set is the lowest value recorded. If the data set contains nondetects, the detection limit represents the minimum value.

^bThe analytical data for Aroclor-1260 could not be fitted. The analytical data set was heavily censored (i.e., there was a large number of samples with no detected analyte). Therefore, the detection limit and maximum detected values were assumed to represent the 0.1 and 99.9 percentiles, respectively.

^cThe soil-screening standard for lead is 400 ppm (EPA, 1994a). No calculations were made in this report for lead contamination.

3.0 EXPOSURE EVALUATION

The exposure assessment for COC-contaminated soil at ER Site 4 was performed using *Précis* to estimate the potential annual radiation dose from radionuclides and the ICR and HI for nonradioactive COC for a "reasonably maximally exposed" individual. This exposure assessment is conservative, meaning the exposure is overestimated.

Précis estimates an individual's annual radiation dose and hazardous chemical intake using a stochastic technique. This method provides an estimate of potential exposures by taking into account the uncertainties inherent in the program input parameters, such as COC concentration, soil density, depth to groundwater, etc. *Précis* evaluates this uncertainty in the exposure using a Latin-hypercube sampling technique that randomly selects trial values for each of the input parameters according to their probability distributions and calculates an exposure concentration for each group of trial values. The resulting output provides a distribution of the individual's annual dose rate and COC intake. As such, the dose, or intake, distribution represents the probability that the individual will receive a specified exposure, assuming that the exposure scenario does occur.

3.1 Radionuclide COC Exposure Evaluation

Evaluation of potential exposures to radionuclides includes assumed pathways for contact with contaminated media. These exposure pathways are based on land-use scenarios for the site.

The industrial land-use scenario was used to evaluate potential radionuclide exposures at ER Site 4. This scenario was evaluated using the *Précis* program under the following exposure assumptions:

- That the individual works exclusively at a randomly chosen location at ER Site 4 for an entire year. This highly conservative assumption was chosen to overestimate worker exposure.
- That the individual does not mitigate his or her potential exposures by avoiding contact with contamination or using personal protective equipment (i.e., the worker is unaware of the existence of contamination).
- That no food is grown at the site and no drinking water well is available at the site.
- That the area of contamination ranged from 1400 to 1900 square meters (m^2). The 1400 m^2 value represents the area contour of maximum COC concentration located near the Surface Impoundment Drainline Outfalls (Figure 2-1b). The 1900 m^2 value represents the area contour in which any COC concentration above background was detected (see Sec. 4.3.3 of this report titled "Results of

the LWDS Remedial Action Field Investigation report). These values were assumed to represent the 0.1 and 99.9th percentiles used in *Précis*.

- That concentration as a function of depth was represented by a lognormal distribution from 0.1 to 99.9th percentiles over the depth range from 0.025 to 1 (m).

Under these assumptions, the exposure pathways are:

- Inhalation of airborne dust
- Ingestion of contaminated soil
- Direct external gamma radiation

The fugitive dust inhalation, incidental soil ingestion, and external gamma radiation exposure pathways were evaluated as shown in Figure 3-1.

3.2 Chemical COC Exposure Evaluation

Evaluation of potential exposures to nonradioactive contaminants was also based on the industrial land-use scenario. The evaluation of exposures of potential workers to nonradioactive chemicals was based on the same assumptions used for exposures to radionuclides (Section 3.1). The airborne dust inhalation and ingestion pathways were evaluated, but the direct external gamma radiation pathway was not included (Figure 3-1).

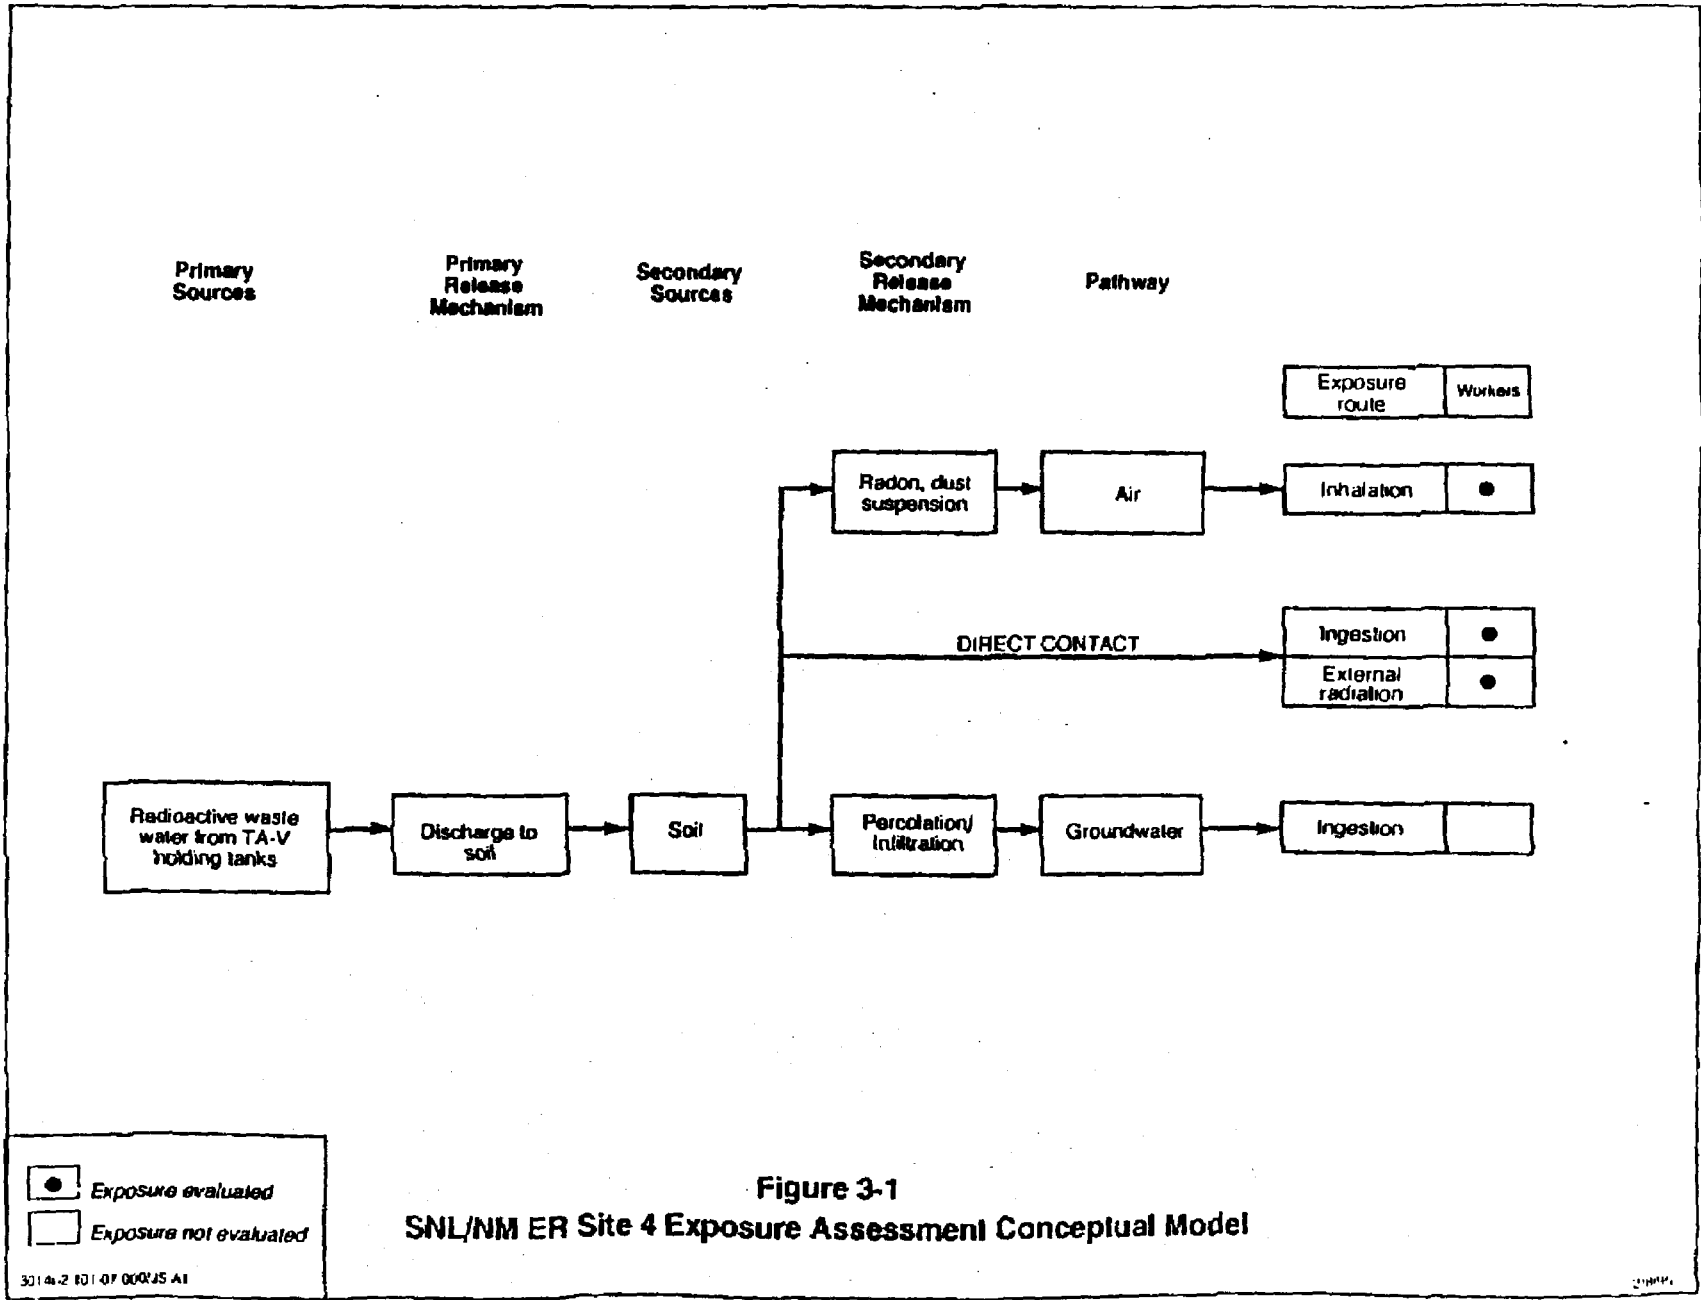

3.3 Sensitivity Analysis of *Précis* Input Parameters

A sensitivity analysis of the uncertainties in *Précis* input parameters was performed to determine which of the input parameters had the greatest influence on the uncertainty of the calculated annual radiation dose or risk.

Probability distributions were developed for *Précis* input parameters specific to SNL/NM (e.g., geological and precipitation parameters) and for certain input parameters related to the worker (e.g., inhalation rate). Measured COC concentrations (Appendix A) were used to describe probability distributions for soil contamination. Preliminary estimates of radiation dose and chemical risks (both carcinogens and noncarcinogens) were made from 100 stochastic *Précis* simulations using the above distributions and the cumulative probability distribution of the estimates was plotted. The three simulations representing the 5, 50, and 95th percentiles of the cumulative probability distribution of the dose and risk estimates were selected as representative of the overall distribution. These three simulations were the basis for the sensitivity evaluation.

Précis performs the sensitivity analysis by systematically varying each input parameter by 1 percent of its value, keeping all other parameters constant, and evaluating the impact of this perturbation on the calculated results. The sensitivities of the calculated results to

6

these small changes in each input parameter were ranked to determine which input parameters introduced the greatest perturbation in the calculated dose. Parameters that did not effect the calculated result by more than 0.05 percent were considered to be nonsensitive and were treated as nonstochastic parameters in subsequent uncertainty calculations.

The parameters contributing the greatest uncertainty in radiation dose estimates were:

- Thickness of the contaminated zone
- Density of the contaminated zone
- Precipitation rate

The parameters contributing the greatest uncertainty in chemical risk estimates were:

- Thickness of the contaminated zone
- Area of the contaminated zone
- Soil ingestion rate

These uncertain parameters, in addition to the COC concentrations in soil, were treated as stochastic variables in subsequent dose calculations.

3.4 Summary of *Précis* Input Parameters

Appendix B summarizes the both the stochastic and nonstochastic input parameters used by *Précis* to calculate the radiation dose, the ICR, and the HI for ER Site 4. Hydrogeologic parameters used were compiled from measurements made at many SNL/NM locations. As such, the values used were not necessarily made at ER Site 4 and reflect the wider range of SNL/NM measurements. This wider range of input parameters represents a conservative overestimation of uncertainty in radiation dose and risk estimates.

4.0 TOXICITY ASSESSMENT

Hazardous materials are classified by their carcinogenic or noncarcinogenic (often termed "systemic") effects on human health. Carcinogenicity risk is described as the probability that an individual will develop cancer at sometime during his or her lifetime from a chronic intake of the carcinogen in question (EPA 1989). Cancer risk for chronic exposure to a carcinogen is described by a slope factor (SF) used to relate the daily carcinogen intake to the cancer risk. The SF values used in this analysis were obtained from the Integrated Risk Information System (IRIS) (EPA 1994b) or from the Health Effects Assessment Summary Tables (HEAST) (EPA 1993).

All radionuclides are classified by the EPA as Group A human carcinogens because of their ionizing radiation emissions. For the purposes of this risk assessment, the cancer risk from radiation is limited by the maximum-allowed radiation dose from exposure from all pathways to 25 mrem/yr (DOE 1988).

Systemic toxicity is described by the reference dose (RfD) concept, which assumes that a threshold level exists for systemic toxicity (EPA 1989). The RfD is the estimate of daily contaminant intake for a human population, including sensitive subpopulations, that is expected to cause no adverse human health effects from chronic exposures. The RfD values used in this analysis were obtained from the IRIS (EPA 1994b).

Toxicity information for each potential chemical of concern at ER Site 4 is summarized in Table 4-1 and described in detail in Appendix C.

Table 4-1

5.0 RISK CHARACTERIZATION OF COCs

The annual radiation dose from potential exposure to radionuclides, the ICR from exposure to carcinogenic chemical contaminants, and the HI for exposure to noncarcinogenic chemicals in soil at the LWDS were calculated using *Précis*. These quantities and their associated uncertainties were estimated from 100 simulations based on industrial land-use scenario assumptions. This risk characterization employs a conservative approach that leads to the overestimation of risk, as described in Section 3.0.

5.1 Radiation Dose Characterization

The maximum radiation dose was calculated to occur in 1994, the year the radionuclides were measured in soil samples (Table 5-1). The 95th percentile of the estimated dose is 23 mrem/year, which is less than the 25 mrem/year regulatory limit (DOE 1988). These radiation dose calculations reflect the highly conservative assumptions as described in Section 3.0. Accordingly, a person working continually at ER Site 4 during 1994 would have had a 95 percent probability of receiving less than the 25 mrem/yr radiation dose limit.

The major contributor to radiation dose was cobalt-60 at the time of maximum dose (1994). Cesium-137, uranium-235, and tritium were minor contributors to the total dose. Direct external radiation was the dominant exposure pathway contributing to dose. Exposure from inhaled airborne dust or ingested soil contributed negligible radiation dose. Appendix D provides the radiation doses from exposure pathways assumed in the land-use scenario. The calculated radiation dose decreases with the decay of radionuclides, resulting primarily from the decay of cobalt-60 with a half-life of 5.27 years (Table 5-1). Thus, a worker employed at ER Site 4 during 2004 would have a 95 percent probability of receiving an estimated radiation dose of approximately 9 mrem/yr or less.

5.2 Risks and Hazards From Exposure to Hazardous Chemicals

The maximum ICR was calculated to occur in 1994, the year the carcinogenic chemicals were measured in soil samples (Table 5-2). The 95th percentile of the estimated ICR is 2.4×10^{-6} , which is above the 1×10^{-6} regulatory limit (EPA 1989).

Dust inhalation and soil ingestion were the dominant exposure pathways contributing to ICR. Exposure from ingested soil contributed negligible cancer risk. Chromium(VI) was the major contributor to ICR, although cadmium and PCBs (aroclor-1260) also contributed appreciably. Appendix D provides the intakes from exposure pathways assumed in the land-use scenario.

The maximum HI was also calculated to occur in 1994 (Table 5-3). The 95th percentile of the estimated HI is 0.04, which is below the 1.0 regulatory limit (EPA 1989). Although the exposure assessment includes conservative assumptions (Section 3.0), a person working continually at ER Site 4 during 1994 would have had a 95 percent probability or greater of

^aThe maximum hazard index was calculated to occur in 1994, the year the samples were taken and analyzed.

Health effects of lead could not be evaluated because the necessary RfD of SF have either not been developed or have been withdrawn (EPA 1994b). A concentration of 400 microgram lead per lead/g soil (ppm) has been provided as a screening level for initiation of risk reduction activities under a residential land-use scenario (EPA 1994a), and higher soil concentrations might be allowed under certain site-specific conditions. All of the lead concentrations measured in soil samples collected at the ER Site 4 LWDS Impoundments are far below 400 ppm (Appendix A).

5.3 Exposure to Buried Radionuclides and Carcinogenic Chemicals

Occupational exposures to radionuclides and noncarcinogenic hazardous chemicals at ER Site 4 are estimated to meet regulatory limits with 95 percent confidence. The estimated ICR associated with exposure to carcinogenic chemicals is greater than the 1×10^{-6} cancer risk considered acceptable by the EPA (EPA 1989). Therefore, the ICRs for exposure to cadmium, chromium(VI), and aroclor-1260 were recalculated using the same *Précis* input parameters, except that a 2-m clean soil cover was assumed (Appendix E). The results of 100 *Précis* simulations showed no calculable cancer risk, indicating that there would be no intake of carcinogenic chemicals under the industrial land-use scenario. Therefore, *Précis* calculated no ICR, in accordance with EPA methodology (EPA 1989).

Although the 95th percentile of the maximum 1994 radiation dose estimate (23 mrem/yr) is less than the 25 mrem/yr regulatory limit, it might be considered that the doses are similar within the uncertainties of the calculations. Therefore, the radiation dose was calculated for radionuclide COC located beneath a 2-m clean soil cover. The maximum radiation dose was calculated to be less than 2×10^{-8} mrem/year at the ground surface (Appendix E).

The 2-m clean soil cover would effectively eliminate the exposure pathways for both radionuclide and chemical COCs under the industrial land-use scenario.

6.0 DISCUSSION

Radiation dose estimates for the industrial land-use scenario (Table 5-1) indicate that the 25 mrem/yr dose limit (assuming maximum dose) would have been met with 95 percent probability in 1994. Because uranium-235 and tritium do not emit appreciable penetrating radiation, these isotopes are insignificant contaminants relative to cobalt-60 and cesium-137. Cobalt-60 contributed the majority of the radiation dose, which is expected to decrease significantly as cobalt-60 decays with a 5.27 year half-life. Thus, the total maximum radiation dose is expected to decrease further below the 25 mrem/yr dose limit to approximately 10 mrem/yr within ten years.

The estimated HI for noncarcinogenic chemicals measured at ER Site 4 under the industrial land-use scenario (see Table 5-3) was less than the specified limit of 1.0 (EPA 1989). Therefore, these metals can be removed from further consideration in remediation decisions at ER Site 4. Because all measured lead concentrations are below the 400 ppm screening level for remediation (EPA, 1994a), lead can be removed from consideration also.

Cadmium, chromium(VI), and PCBs (aroclor-1260) contributed significantly to the ICR under the industrial land-use scenario (Appendix D). The 95th percentile of the estimated ICR is 2.4×10^{-6} (see Table 5-2), which is above the 1×10^{-6} regulatory limit (EPA 1989). If 2 meters of clean cover are applied to the site, the ICR would be far less than the 1×10^{-6} risk considered acceptable (EPA 1989). A 2-m clean soil cover would also reduce the radiation dose from radionuclides to far less than the 25 mrem/yr regulatory limit (DOE 1988).

6.1 Uncertainty

The parameters contributing the greatest uncertainty in radiation dose estimates were the thickness of the contaminated zone, the density of the contaminated soil, and the precipitation rate. The thickness and density of the contaminated zone are closely associated with the gamma radiation shielding provided by soil. Although the precipitation rate is not directly related to gamma shielding, infiltration of rain water through soil provides a mechanism for leaching gamma emitters from soil and removing dissolved radionuclides below the surface soil, thus providing for increased shielding.

The parameters contributing the greatest uncertainty in ICR estimates for chemical COCs were the thickness of the contaminated zone, the area of the contaminated zone, and the soil ingestion rate. These three parameters are closely associated with the accessibility of the exposed individual to contamination. This result indicates that the *Précis* model (when applied under the industrial land-use scenario) might be more sensitive to uncertainties in soil ingestion parameters than the combined uncertainties in parameters related to contaminant dispersion or dust inhalation (e.g., wind speed).

6.2 Conclusions

Radiation dose, ICR, and HI values were calculated using conservative worker exposure assumptions. The results indicate that cesium-137, cobalt-60, tritium, uranium-235, barium, chromium (III), lead, nickel, and zinc can be removed from further consideration at the ER Site 4 LWDS Impoundments. Based on these calculations and the measured concentrations of cadmium, and chromium (VI), and PCBs (aroclor-1260) in soil, remediation decisions might be required to reduce the estimated cancer risk at ER Site 4. Further evaluation showed that cadmium, chromium (VI), PCBs, and all other COC measured at ER Site 4 would meet regulatory limits and could be removed from further consideration if a 2-m clean soil cover was added to the site.

**                               Parameter Summary                               **
**
*****
Area of contaminated zone = 1554 square meters
LHS Settings: Lognormal-B      1400      1900
Justification: 1400 m2 is the area contour of maximum COC concentration
located near the Drainline Outfall (Figure 2-1b). 1900 m2 is the area
contour in which any COC concentration was detected.

Thickness of cover zone = 0 meters

Density of cover zone = 1.6 grams/cm**3
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Radon diffusion coefficient (cover) = 2e-06 meters/sec
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Radon diffusion coefficient (contaminated) = 2e-06 meters/sec
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Depth of soil mixing area = 0.15 meters
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Radon emanation factor = 0.2
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Occupancy and shielding factor, external gamma = 0.496157
LHS Settings: Normal-B      0.23      0.33
Justification: Calculated assuming 10 to 50% outdoor occupancy onsite,
25 to 50% indoor occupancy at 70% outside exposure Yu, 1992.

Occupancy factor, dust inhalation = 0.489403
LHS Settings: Normal-B      0.3      0.6
Justification: Calculated assuming 10 to 50% outdoor occupancy onsite,
25 to 50% indoor occupancy at 40% outside exposure Yu, 1992.

Fraction of time outdoors = 0.25
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Shape factor for external gamma = 1
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Hydraulic gradient of saturated zone = 0.02
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Radon vertical dimension of mixing = 2 meters
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Inhalation rate = 9496.96 meters**3/year
LHS Settings: Normal-B      3600      1.1e+04
Justification: EPA, 1989

```

Length parallel to aquifer flow = 57.4 meters
Justification: Nonstochastic parameter correlated to the contamination area
Yu, 1992.

Dilution length for inhalation = 3 meters
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Mass loading for inhalation = 4.41948e-05 grams/meter**3
LHS Settings: Lognormal-B 9e-06 0.0004
Justification: Yu, 1992.

Fractional water content (cover) = 0.05
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Soil ingestion rate = 18.25 grams/year
Justification: EPA, 1989

Thickness of contaminated zone = 0.173995 meters
LHS Settings: Lognormal-B 0.025 1
Justification: Surface contamination from approx. 1 inch to approx. 3 ft.

Erosion rate of contaminated zone = 1e-09 meters/year
Justification: Conservative assumption to overestimate retention of
contamination on the site.

Average annual wind speed = 2 meters/sec
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Basic Radiation Dose Limit = 25 millirem/year
Justification: DOE, 1988

Time since placed = 0 years

Time step - 1 = 1 years
Time step - 2 = 3 years
Time step - 3 = 5 years
Time step - 4 = 10 years
Time step - 5 = 30 years
Time step - 6 = 100 years
Time step - 7 = 300 years
Time step - 8 = 500 years
Time step - 9 = 1000 years

Soil b-parameter of contaminated zone = 2.99888
LHS Settings: Lognormal-B 0.4 10.3
Justification: SNL/NM, 1991. Monitoring Well MW-4, Chemical Waste Landfill.

Soil b-parameter of saturated zone = 5.3
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Soil b-parameter of unsaturated zone = 5.3
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Density of contaminated zone = 1.48044 grams/cm**3
LHS Settings: Normal-B 1.3 1.7
Justification: Yu et al. 1992.

Density of saturated zone = 1.6 grams/cm**3
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Density of unsaturated zone = 1.6 grams/cm**3
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Effective porosity of contaminated zone = 0.207437
LHS Settings: Normal-B 0.13 0.3
Justification: Yu et al. 1992.

Effective porosity of saturated zone = 0.2
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Effective porosity of unsaturated zone = 0.2
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Thickness of unsaturated zone = 125 meters
Justification: Conservative (lower) value measure at the Chemical Waste
Landfill SNL/NM, 1991.

Hydraulic conductivity of contaminated zone = 100 meters/year
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Hydraulic conductivity of saturated zone = 100 meters/year
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Hydraulic conductivity of unsaturated zone = 100 meters/year
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Total porosity of contaminated zone = 0.4
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Total porosity of saturated zone = 0.489796
LHS Settings: Normal-B 0.24 0.57
Justification: Yu et al., 1992.

Total porosity of unsaturated zone = 0.4
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Total porosity of cover material = 0.4
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Evapotranspiration Coefficient = 0
Justification: Conservative assumption in which no water is evaporated and
all precipitation is assigned to infiltration.

Precipitation = 0.00460367 meters/year
LRS Settings: Lognormal-B 0.0009 0.02
Justification: Conservative assumption in which all precipitation is assigned to infiltration.

Shape Parameters (0.564 m) = 1
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Shape Parameters (1.784 m) = 1
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Shape Parameters (2.523 m) = 1
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Shape Parameters (3.989 m) = 1
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Shape Parameters (5.642 m) = 1
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Shape Parameters (7.979 m) = 1
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Shape Parameters (12.62 m) = 1
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Shape Parameters (17.84 m) = 1
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Shape Parameters (39.89 m) = 1
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Shape Parameters (56.42 m) = 1
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Shape Parameters (178.4 m) = 0
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Shape Parameters (564.2 m) = 0
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Time since placement for guidelines = 0 years

 **
 ** Parameter Summary **
 **

Area of contaminated zone = 1550 square meters
 LHS Settings: Lognormal-B 1400 1900
 Justification: 1400 m² is the area contour of maximum COC concentration located near the Drainline Outfall (Figure 2-1b). 1900 m² is the area contour in which any COC concentration was detected.

Thickness of cover zone = 0 meters

Density of cover zone = 1.57875 grams/cm^{**3}
 LHS Settings: Normal-B 1.3 1.7
 Justification: Yu et al. 1992.

Depth of soil mixing area = 0.15 meters
 Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Fraction of time spent indoors = 0.5
 Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Occupancy factor, dust inhalation = 0.589704
 LHS Settings: Normal-B 0.3 0.6
 Justification: Calculated assuming 10 to 50% outdoor occupancy onsite, 25 to 50% indoor occupancy at 40% outside exposure Yu, 1992.

Fraction of time outdoors = 0.25
 Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Hydraulic gradient of saturated zone = 0.02
 Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Inhalation rate = 4343.05 meters^{**3}/year
 LHS Settings: Normal-B 3600 1.1e+04
 Justification: EPA, 1989, Yu et al, 1992.

Length parallel to aquifer flow = 55 meters
 LHS Settings: Lognormal-B 54.5 60.3
 Justification: Correlated to the contamination area.

Dilution length for inhalation = 1.84955 meters
 LHS Settings: Lognormal-B 0.03 250
 Justification: Gilbert et al, 1989.

Mass loading for inhalation = 0.000108647 grams/meter^{**3}
 LHS Settings: Uniform 9e-06 0.0004
 Justification: Yu et al, 1992.

Soil ingestion rate = 10 grams/year
 LHS Settings: Normal-B 0.0365 12.5
 Justification: EPA, 1989

Thickness of contaminated zone = 0.107951 meters
 LHS Settings: Lognormal-B 0.025 0.61
 Justification: Assumed surface contamination from approx. 1 inch to 2 ft.

Erosion rate of contaminated zone = 1e-09 meters/year
Justification: Conservative assumption to overestimate retention of contamination on the site.

Time since placed = 0 years

Time step - 1 = 1 years
Time step - 2 = 3 years
Time step - 3 = 5 years
Time step - 4 = 10 years
Time step - 5 = 20 years
Time step - 6 = 30 years
Time step - 7 = 100 years
Time step - 8 = 300 years
Time step - 9 = 500 years

Soil b-parameter of contaminated zone = 5.3
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Soil b-parameter of saturated zone = 5.3
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Soil b-parameter of unsaturated zone = 5.3
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Density of contaminated zone = 1.49595 grams/cm**3
LHS Settings: Normal-B 1.3 1.7
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Density of saturated zone = 1.6 grams/cm**3
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Density of unsaturated zone = 1.6 grams/cm**3
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Effective porosity of contaminated zone = 0.2
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Effective porosity of saturated zone = 0.2
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Effective porosity of unsaturated zone = 0.2
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Thickness of unsaturated zone = 137.604 meters
LHS Settings: Normal-B 124.7 150.9
Justification: Measurements made at the Chemical Waste Landfill SNL/NM, 1991.

Hydraulic conductivity of contaminated zone = 100 meters/year
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Hydraulic conductivity of saturated zone = 100 meters/year
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Hydraulic conductivity of unsaturated zone = 100 meters/year
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Total porosity of contaminated zone = 0.4
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Total porosity of saturated zone = 0.4
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Total porosity of unsaturated zone = 0.4
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Evapotranspiration Coefficient = 0
Justification: Conservative assumption in which no water is evaporated and
all precipitation is assigned to infiltration.

Precipitation = 0.00459136 meters/year
LHS Settings: Lognormal-B 0.0009 0.02
Justification: Conservative assumption in which all precipitation is
assigned to infiltration.

Time since placement for guidelines = 0 years

Basic Cancer Risk Limit = $1e-06$
Justification: EPA, 1989

Basic Hazard Index Limit = 1
Justification: EPA, 1989

Basic Chemical Intake Limit = 100 mg/kg-day

 **
 ** Parameter Summary **
 **

Area of contaminated zone = 1550 square meters
 LHS Settings: Lognormal-B 1400 1900
 Justification: 1400 m² is the area contour of maximum COC concentration located near the Drainline Outfall (Figure 2-1b). 1900 m² is the area contour in which any COC concentration was detected.

Thickness of cover zone = 0 meters

Density of cover zone = 1.61204 grams/cm³
 LHS Settings: Normal-B 1.3 1.7
 Justification: Yu et al, 1992.

Depth of soil mixing area = 0.15 meters
 Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Fraction of time spent indoors = 0.5
 Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Occupancy factor, dust inhalation = 0.354503
 LHS Settings: Normal-B 0.3 0.6
 Justification: Calculated assuming 10 to 50% outdoor occupancy onsite, 25 to 50% indoor occupancy at 40% outside exposure Yu, 1992.

Fraction of time outdoors = 0.25
 Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Hydraulic gradient of saturated zone = 0.02
 Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Inhalation rate = 7003.86 meters³/year
 LHS Settings: Normal-B 3600 1.1e+04
 Justification: EPA, 1989; Yu et al, 1992.

Length parallel to aquifer flow = 56.3345 meters
 Justification: Correlated to the contamination area.

Dilution length for inhalation = 4.22974 meters
 LHS Settings: Lognormal-B 0.03 250
 Justification: Gilbert et al, 1989.

Mass loading for inhalation = 0.000352143 grams/meter³
 LHS Settings: Uniform 9e-06 0.0004
 Justification: Yu et al, 1992.

Soil ingestion rate = 10 grams/year
LHS Settings: Normal-B 0.0365 12.5
Justification: EPA, 1989

Thickness of contaminated zone = 0.10084 meters
LHS Settings: Lognormal-B 0.025 0.61
Justification: Assumed surface contamination from approx. 1 inch to 2 ft.

Erosion rate of contaminated zone = 1e-09 meters/year
Justification: Conservative assumption to overestimate retention of contamination on the site.

Time since placed = 0 years

Time step - 1 = 1 years
Time step - 2 = 5 years
Time step - 3 = 10 years
Time step - 4 = 20 years
Time step - 5 = 30 years
Time step - 6 = 100 years
Time step - 7 = 300 years
Time step - 8 = 500 years
Time step - 9 = 1000 years

Soil b-parameter of contaminated zone = 5.3
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Soil b-parameter of saturated zone = 5.3
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Soil b-parameter of unsaturated zone = 5.3
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Density of contaminated zone = 1.40021 grams/cm**3
LHS Settings: Normal-B 1.3 1.7
Justification: Yu et al, 1992.

Density of saturated zone = 1.6 grams/cm**3
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Density of unsaturated zone = 1.6 grams/cm**3
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Effective porosity of contaminated zone = 0.2
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Effective porosity of saturated zone = 0.2
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Effective porosity of unsaturated zone = 0.2
Justification: Precis default, nonstochastic parameter consistent with SNL/NM-specific value.

Thickness of unsaturated zone = 144.469 meters
LHS Settings: Normal-B 124.7 150.9
Justification: Measurements made at the Chemical Waste Landfill
SNL/NM, 1991.

Hydraulic conductivity of contaminated zone = 100 meters/year
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Hydraulic conductivity of saturated zone = 100 meters/year
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Hydraulic conductivity of unsaturated zone = 100 meters/year
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Total porosity of contaminated zone = 0.4
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Total porosity of saturated zone = 0.4
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Total porosity of unsaturated zone = 0.4
Justification: Precis default, nonstochastic parameter
consistent with SNL/NM-specific value.

Evapotranspiration Coefficient = 0
Justification: Conservative assumption in which no water is evaporated and
all precipitation is assigned to infiltration.

Precipitation = 0.00459136 meters/year
LHS Settings: Lognormal-B 0.0009 0.02
Justification: Conservative assumption in which all precipitation is
assigned to infiltration.

Time since placement for guidelines = 0 years

APPENDIX C
TOXICITY PROFILES FOR CONSTITUENTS OF CONCERN

Tritium

Tritium (H-3) is both a primordial and anthropogenic isotope. Tritium decays with a half-life of 12.3 years and emits only low-energy beta radiation. Tritium has no radioactive daughters. Tritium is readily oxidized in the environment and exchanged with water to form HTO (NCRP 1979). As a result, HTO is quickly and completely absorbed by inhalation, ingestion, and by direct contact with the skin. Absorbed HTO is distributed uniformly in the body and is eliminated with a half-times of approximately 10 days, primarily by urinary excretion (NCRP 1979).

Uranium-235

Uranium-235 is either a natural or anthropogenic isotope and is the parent of a long decay chain. Uranium-235 is primarily an alpha emitter with a half-life of 7.0×10^8 years. Retention of inhaled uranium compounds is determined by solubility. Inhaled insoluble compounds are retained in lung for long periods of time. Soluble compounds are readily absorbed into blood. Of the absorbed uranium, approximately 12 percent is translocated to kidney and 20 percent is translocated to bone. An additional 12 percent is distributed throughout the body and the remainder is excreted (ICRP 1979). Ingested soluble uranium compounds behave in the same manner; but are only poorly absorbed to blood from the gastrointestinal tract.

CHEMICAL CONTAMINANTS

Barium, CASRN 7440-39-3

Barium is relatively abundant in nature and occurs in plant and animal tissue. From soluble compounds, barium is absorbed in small quantities into the human body and retained there. The daily intake is about 0.75 mg, but the retention time is short, probably less than a day (ICRP 1975). The considerable oral toxicity of barium is usually masked by the low solubility of most barium compounds. In soluble form, however, it leads to gastroenteritis and effects on the heartbeat, up to and including ventricular fibrillations (Doull et al. 1991). By inhalation, barium ores lead to mild pneumoconiosis, which is usually reversible after termination of exposure.

Cadmium, CASRN 7440-43-9

Cadmium is a metal that has toxic effects similar to those of lead and its compounds. It is present in most foods and tissues, leading to an average daily intake of about 0.2 mg (ICRP 1975). Intake of cadmium and its compounds can occur by inhalation or ingestion. The kidney is the most sensitive organ and is damaged by excessive loss of both low and high molecular mass proteins (proteinuria). A number of effects in other organs, such as the lung, have also been reported. In the lung, tissue loss occurs at high exposures and chronic tissue inflammation occurs at lower levels, leading to emphysematous and fibrotic changes (Doull et al. 1991).

There is sufficient evidence of carcinogenicity in humans to classify cadmium as a Class B1 inhalation carcinogen. Although excess lung cancer risks were observed in epidemiological

Classification of Human Carcinogens

A classification system for carcinogens describes uncertainties in available epidemiological and toxicological data. This "weight of evidence" classification is based on the thoroughness and appropriateness of available data. The classification system is as follows (EPA 1994):

Classification Group	Description
A	Human Carcinogen
B1 available	Probable human carcinogen; limited human data
B2	Probable human carcinogen; based on animal data only
C	Possible human carcinogen
D	Not classifiable as to human carcinogenicity
E	Evidence of noncarcinogenicity to humans.

All radionuclides are considered to be carcinogens (Group A). The carcinogenicity of radionuclides is assumed to exceed their systemic toxicity (EPA 1994).

RADIONUCLIDE CONTAMINANTS

Cesium-137

Although this fission product is a pure beta emitter, its short lived daughter barium-137m, is a high energy, high intensity gamma emitter. This daughter makes cesium-137 an important external exposure hazard. Cesium-137 has a physical half-life of 30.2 years. Cesium that is inhaled or ingested is readily and almost completely absorbed into blood and distributed uniformly in the body. Approximately 10 percent of absorbed cesium is cleared form the body with a half-time of approximately 2 days and the remaining 90 percent is cleared with a half-time of approximately 110 days (ICRP 1979).

Cobalt-60

Cobalt-60 emits high energy gamma radiation. Therefore, the radionuclide is an important external exposure hazard. Cobalt-60 has a physical half-life of 5.27 years. Inhaled insoluble cobalt compounds are retained in lung for long periods of time. Soluble cobalt compounds that are ingested are only poorly absorbed into the body. For the purposes of evaluating radiation dose, it is assumed that approximately 80 percent of the absorbed cobalt is located in the liver and the remaining 20 percent is uniformly distributed throughout the rest of the body. This cobalt located in tissues other than lung is assumed to be removed from the body with half-times of 6 to 800 days (ICRP 1979).

PCBs, CASRN 1336-36-3

The class of PCBs consists of a number of different mixtures of many isomers, with chlorine contents ranging from 10 to 70 percent. The acute health effects of PCB fall into two classes; skin effects and toxic action on the liver. A suspected delayed effect is cancer of the liver (Class B2). The effect on the skin is a painful condition called chloracne. The skin and hepatotoxic action of PCBs increases with the chlorine content of the mixture. For aroclor-1260 the chlorine content is about 60 percent (Doull et al. 1991).

Zinc, CASRN 7440-66-6

Zinc is an essential trace nutrient in the human diet and occurs widely in foodstuffs, particularly in meats, seafood, dairy products, and vegetables. The daily intake of zinc through the diet is 6 to 40 mg (ICRP 1975). Some zinc compounds are of low toxicity; but acute exposures can cause dermatitis upon skin contact and intestinal disorders upon ingestion. "Metal fume fever" has been observed upon high-level inhalation exposures, however, no chronic effects of zinc inhalation have been reported. Although some zinc compounds are suspected to be carcinogenic, no slope factors are available. Elemental zinc in itself is not a human carcinogen (Class D) (EPA 1994).

U.S. Environmental Protection Agency (EPA), 1994. Integrated Risk Information System (IRIS) Data File, U.S. Department of Health and Human Services, National Library of Medicine Toxicology Data Network (TOXNET), Bethesda, Maryland.

studies, confounding factors, such as smoking, were not sufficiently accounted for to support classification as a Class A carcinogen. There is no evidence for carcinogenicity associated with chronic cadmium ingestion.

Chromium(III), CASRN 16065-83-1

Although chromium exists in several valence states, only the trivalent and hexavalent states are biologically significant. Chromium(III) compounds are less toxic than chromium(VI) forms. There is no evidence that chromium(III) is converted to chromium(VI) in biological systems. Chromium(III) is a systemic toxicant to the kidney. Acute exposure to either trivalent or hexavalent chromium compounds causes dermatitis, penetrating ulcers on the hands and forearms, perforation of the nasal septum, and inflammation of the larynx and liver (Doull et al. 1991).

Chromium(VI), CASRN 18540-29-9

Chromium(VI) is a Class A carcinogen (EPA 1994). Epidemiologic studies indicate that inhalation exposure to chromate results in bronchogenic carcinoma. The relative risk to chromate plant workers in the development of respiratory cancer is greater than in the general population (Doull et al. 1991).

Lead and Inorganic Lead Compounds, CASRN 7439-92-1

The toxicity of lead and its compounds has been investigated extensively. Lead is a contaminant in most foods, resulting in a daily intake of about 0.4 mg (ICRP 1975). Toxic effects of lead to the central nervous system, the peripheral nervous system, the kidneys, and the blood have been reported. Because its toxicity apparently does not exhibit a threshold, the EPA has published no oral RfDs for lead.

There is sufficient evidence of carcinogenicity in animal experiments with lead compounds to classify lead and its inorganic compounds as probable human carcinogens, Class B2. Kidney tumors were observed in these experiments at high doses. However, as a result of dosimetry uncertainties, no estimates for the slope factors are available at present.

Nickel and Soluble Salts, CASRN 117-81-7

Nickel occurs in the normal human diet, particularly vegetables and grains. Daily mean dietary intake is 0.2 to 0.6 mg (ICRP 1975). At high exposure levels, nickel is a skin irritant and ingestion leads to intestinal disorders. The systemic toxicity of nickel depends strongly on its chemical form. Nickel carbonyl is a highly toxic vapor, while other forms are only moderately toxic by ingestion (Doull et al. 1991).

Some nickel compounds, such as nickel carbonyl and nickel subsulfide, are designated as Class A carcinogens based on lung and nasal cancer observed in nickel refinery workers. These observations have been confirmed in laboratory animal experiments. No slope factor for nickel ingestion is available.

APPENDIX D

**ANNUAL RADIATION DOSES FROM RADIONUCLIDES AND
DAILY INTAKES OF HAZARDOUS CHEMICALS FOR
EXPOSURE PATHWAYS ASSUMED IN THE
INDUSTRIAL LAND-USE SCENARIO**

Exposure Pathways

The following example output is from one of the 100 *Précis* simulations described in Section 5.0. As such, the numerical values do not appear in the main text except as included in Tables 5-1 through 5-3.

The exposure pathways shown in the example output are related to the exposure pathways in the conceptual model (Figure 3-1) as follows:

- the *Ground* pathway in the example is the *External Radiation* exposure pathway in Figure 3-1,
- the *Dust* and *Radon* pathways in the example is the *Inhalation* exposure pathway in Figure 3-1, and
- the *Soil* pathway in the example is the *Ingestion* exposure pathway in Figure 3-1.

Because radon is a uranium daughter, the *Radon* inhalation pathway was included for uranium dose estimates but was excluded from cobalt-60, cesium-137, and tritium dose estimates. The *Plant*, *Meat*, *Milk*, *Water*, and *Fish* ingestion pathways below are excluded under the industrial land-use scenario assumptions (Section 3.0).

Appendix A

General Field Procedures

APPENDIX A GENERAL FIELD PROCEDURES

A.1 Radioactive Screening

All field operations conducted at the Liquid Waste Disposal System (LWDS) were supported full-time by qualified health-physics technicians from Department 7714, Radiation Protection. Field screening for radioactive contamination was continuous and included:

- Collecting swipe samples for loose surface contamination,
- Screening with hand-held radiacs for general radiation levels and total surface contamination, and
- Monitoring for airborne radioactive contamination with both general-area and personal air-sampling devices.

All radioactive screening was conducted in accordance with Department 7714-approved procedures.

A.2 Subsurface Soil Sampling

The first sixteen soil borings were drilled with a Barber 70E drill rig modified to use a rotasonic method. Sonic drilling consists of a truck-mounted drill rig with a sonic head that transmits a 10,000-cycle per minute vibration to the core bit through the quill, drill string, and core barrel. Vibrations are generated by two synchronized eccentrics that rotate in opposite directions. Forces cancel each other in the horizontal movements and reinforce each other in the vertical. A diamond button core-bit was attached to the bottom of the core barrel. The drill string was rotated while coring to expose the core-bit's buttons to the full annular area. Four-inch core was collected with a 10-ft steel sample barrel; material under the core-bit was pulverized by the vibrations and moved sideways in the borehole.

The benefit of the rotasonic method is that it does not generate soil cuttings. The drill cuttings are displaced outward in the borehole, not returned to the surface, thus reducing the potential for waste generation. After the potential to generate mixed

waste was better understood, the final two borings were completed using a Failing F-10 auger rig.

Continuous core samples were collected with a 4-in. hollow-stem auger or sonic core barrel. After retrieval, the core samples were immediately sampled for volatile organic contaminants (VOCs) coincident with screening for volatile organics using an organic vapor analyzer (OVA) flame ionization detector (FID), and screened for radioactivity using both the pancake Geiger Müller (GM) detector and a sodium-iodide (NaI) detector.

All cores were photographed and the lithology was described. The core was geologically logged by the U.S. Geological Survey (USGS). The visual characterization included composition of the framework, matrix, bedding, texture, soil moisture, and color, as outlined in Field Operating Procedure (FOP) 94-05 (SNL, 1994a).

Samples for radioactive and chemical analyses were collected from the core at discrete intervals using a stainless-steel trowel that was decontaminated between samples. The samples were placed directly into appropriate sample containers. The core barrels and sampling equipment were decontaminated between each retrieved sample core.

Drill cuttings were placed in appropriate containers dependent upon the expected waste characterization. The boreholes were backfilled to the surface with a mixture of bentonite cement and grout upon completion of the sampling. The grout mixture was added to the bottom of the boring with a tremie pipe as the augers were slowly retracted. To eliminate the potential for hole collapse and ensure the placement of a continuous grout plug, the tremie pipe was maintained below the grout surface.

A.3 Monitoring Well Installation

Monitoring well installation procedures are identical to those described for subsurface soil sampling, with the exception that a Dresser rig was used in place of the original Barber rig. The retrieved core samples were also screened for saturation and grain size to identify any perched zone and subsequent confining layer. If a possible perched zone was identified, drilling stopped and the auger and overshot casing were retracted approximately 2 ft. Operations were held for at least 60 min (usually overnight) to allow

ground water to recharge into the open borehole. Water levels were recorded during the waiting period. Although several possible perched zones were identified, no actual perch zones were encountered. All ground-water monitoring wells were completed at the water table.

Monitoring well LWDS-MW2 was screened with Type 304 stainless-steel as required in the LWDS RCRA Facility Investigation (RFI) work plan (SNL, 1994b). Monitoring well LWDS-MW1 was completed several months after LWDS-MW2. During this time, there was considerable controversy regarding the possible presence of chromium at the Chemical Waste Landfill (CWL). Steel-constructed screens were identified as a possible contributor to the chromium contamination. LWDS-MW1 was completed entirely with Schedule 80 polyvinyl chloride (PVC) pipe to avoid this issue. Each monitoring well was constructed with a 5-ft sump. The sand filter pack was designed based on a sieve grain-size analysis of the aquifer soil. Figures A-1 and A-2 show cross-sectional views of the monitoring wells' construction.

In each well, the remaining riser to the surface was constructed of PVC pipe. All joints were flush threaded and a rubber gasket was placed at each coupling to prevent grout seepage into the well. No adhesives, glues, grease, or their agents were used to secure the couplings. A 10-ft bentonite seal was installed over the filter pack. The bentonite seal was pumped through the tremie pipe using a mixture of a high-viscosity slurry and finely ground bentonite flakes. A select mixture of uniform volclay grout was pumped from the bentonite seal to the ground level to minimize the potential contamination problems during well development. The initial grout mixture was installed in a 20-ft lift using a tremie pipe and allowed to harden for at least 12 hr. The remaining grout was then pumped to the surface. The drill casing was retracted in conjunction with installation of the annular materials to eliminate the potential for borehole collapse.

A 3-ft by 3-ft, 4-in.-thick sloped concrete pad was constructed around each monitoring well. Three 2-in., concrete-filled steel posts are equally spaced around LWDS-MW2. LWDS-MW1, which is in the TA-V parking lot, is sloped to the surrounding pavement.

All development activities were performed in accordance with applicable Environmental Restoration (ER) Project procedures. To reduce the large quantities of water introduced by jetting, swabbing and bailing methods were used for development. Well purging was

Figure A-2. Cross-Sectional View of Liquid Waste Disposal System Monitoring Well 1 (LWDS-MW1)

accomplished with a submersible pump. The criteria for the completion of well development were based on consistent measurements of pH, conductivity, temperature, and turbidity. Ground-water sampling was performed in accordance with procedures set forth in the *LWDS Ground-Water Sampling and Analysis Plan* (IT, 1994).

Each monitoring well was surveyed for piezometric surface, total depth, and surface elevation. Horizontal and vertical (longitudinal and latitudinal, and elevation) coordinates were surveyed by a certified contractor survey crew with a field team manager overseeing the work. The survey elevations are included in the well construction diagrams (Figures A-1 and A-2).

A.4 Equipment Decontamination

Equipment decontamination was conducted in accordance with FOP 94-26 (SNL, 1994c). All equipment was thoroughly decontaminated between drilling operations and sampling events, and monitored for radioactive contamination. Personnel decontaminated the drilling equipment prior to each use, after drilling each monitoring well, and after completing all drilling activities. The drilling equipment was cleaned with a high-pressure steam cleaner and rinsed with clean water. All reusable sampling utensils were cleaned with trisodium phosphate (TSP) detergent and water, followed by repeated rinsing with distilled water.

A.5 Geological Data Collection

Geologic data were described and recorded following guidelines described in FOP 94-05 (SNL, 1994a). The guidelines describe unconsolidated sediments retrieved as cores and cuttings and include:

- Name of unconsolidated sediment (sand, pebbles, cobbles, etc.).
- Texture as indicated by grain-size distribution (American Geological Institute, 1989, Data Sheet 19.1), particle shape (Compton, 1962), sorting (Compton, 1962), grading, packing (American Geological Institute, 1989, Data Sheets 23.1 and 23.2), and fabric.
- Composition (mineralogy) of larger-grained sediments.
- Color using the rock-color chart (Goddard and others, 1984, 1991).
- Sedimentary structures.

- Degree of consolidation and cementation, presence of caliche or calcium carbonate, reaction with 10 percent hydrochloric acid (HCl).
- Moisture content.
- Description of basal contact.

These lithologic descriptors were limited to those readily visible to the eye or with the use of a 10X hand lens.

In addition to lithologic descriptions, other field observations were made. These observations are reported as written communication, U.S. Geological Survey, Liquid Waste Disposal System Well Installation, Field Notes (1993), and may be accessed through SNL, Environmental Operations Records Center, Albuquerque, New Mexico.

A suite of geophysical logging techniques provided an approximate representation of the borehole lithology, the location of the water table, and other unsaturated zone characteristics. These techniques included gamma-gamma log, neutron log, and induction log.

The gamma-gamma instrument consisted of a 20-Ci americium-241 gamma source with a single detector. With this technique, measured readings in counts per second (cps) are converted by calibration to apparent density values in grams per cubic centimeter (gm/cc). Calibration was conducted before and after logging using blocks of acrylic (1.4 gm/cc) and aluminum (2.65 gm/cc). The gamma-gamma log provided information relative to formation densities within the vicinity of the borehole wall.

Data from the neutron log were used to identify relative porosity values of the formation. A decrease in American Petroleum Institute (API) units represents an increase in relative formation porosity. The neutron tool consists of a 3-Ci americium-241/beryllium (Am-241 Be) neutron source and an epithermal neutron detector. The noncompensating (single-detection) 1-11/16-in. tool used is an omnidirectional instrument that also records data in counts per second. The recorded cps units are converted to API units by normalizing to known and established values.

The induction log measurements were used to assist in identifying lithologic features and water content contrasts.

Appendix B
Analytical Program

APPENDIX B ANALYTICAL PROGRAM

The analytical program was devised to evaluate all constituents that were thought to be prevalent in the liquid waste from Technical Area V (TA-V) and some additional compounds possibly discharged when the U.S. Air Force (USAF) used the site. Table B-1 lists the common groupings of the Liquid Waste Disposal System (LWDS) constituents of concern (COCs) and associated analytical methods. Sections B.1 through B.3 further describe the test methods used for the analysis of soil and ground-water samples collected at the site.

Table B-1
Constituents of Concern at the LWDS

Constituent	Analytical Method
Radionuclides	Gamma spectroscopy (for gamma emitters) and EPA Test Method H-01 (for tritium)
Volatile Organic Contaminants (VOCs)	EPA Test Method 8240
Semi-Volatile Organic Contaminants (SVOCs)	EPA Test Method 8270
Metals	Target analyte list (TAL) metals (EPA Test Methods 6010, 7061, 7421, 7470, 7741 and 7841)
Polychlorinated Biphenyls (PCBs)	EPA Test Method 8080

B. 1 Organics

All soil and ground-water samples collected during the LWDS investigation were analyzed for volatile organic contaminants (VOCs) via U.S. Environmental Protection Agency (EPA) Test Method 8240 and for SVOCs via EPA Test Method 8270. As a result of the historical review of impoundment activities, selected samples were also analyzed for polychlorinated biphenyls (PCBs) via EPA Test Method 8080.

Ground-water samples from well LWDS-MW1 were initially analyzed for VOCs via EPA Test Method 8240, which includes both gas chromatography and mass spectrometry analyses. This test method typically has a quantitation limit of 5 micrograms per liter

(µg/L) or parts per billion (ppb), and historically has been preferred because the presence of organic constituents is verified by a second analytical instrument. Following the identification of trichloroethene (TCE) in well LWDS-MW1 in early 1994, SNL/NM switched to EPA Test Method 8010 for VOCs, which utilizes gas chromatography alone. The detection limit for this analytical method is 0.5 ppb. Verification of sample constituents is achieved by performing a second analysis.

B.2 Metals

Soil and ground-water samples were analyzed for the target analyte list (TAL) metals identified in 40 CFR Part 264 and chromium-VI in some cases. Table B-2 presents a complete list of the metals analyzed and their detection limits.

B.3 Radionuclides

Soil samples were evaluated for the presence of gamma-emitting radionuclides through the use of a one-hour count gamma spectroscopy and for the presence of tritium by EPA Test Method H-01.

**Table B-2
Metals Analyses at the LWDS**

Metal	EPA Test Method	Detection Limit (mg/kg)
Aluminum	6010	0.20
Antimony	6010	0.60

CERTIFIED MAIL - RETURN RECEIPT REQUESTED

Mr. Robert S. (Stu) Dinwiddie, Manager
New Mexico Environment Department
Hazardous and Radioactive Materials Bureau
RCRA Permits Management Program
2044 Galisteo Street
P.O. Box 26110
Santa Fe, NM 87505-2100

Dear Mr. Dinwiddie:

Enclosed are two copies of the Department Of Energy/Sandia National Laboratories response to the NMED Request for Supplemental Information (RSI), dated September 30, 1997, for the Liquid Waste Disposal System (LWDS) RCRA Facility Investigation.

If you have any questions, please contact John Gould at (505) 845-6089, or Mark Jackson at (505) 845-6288.

Sincerely,

A handwritten signature in cursive script that reads "George K. Jackson".

for Michael J. Zamorski
Acting Area Manager

Enclosures

**Request for Supplemental Information:
Results of the Liquid Waste Disposal System RCRA Facility Investigation,
Sandia National Laboratories, Albuquerque, New Mexico**

For purposes of clarity, text has been excerpted from the results of the Liquid Waste Disposal System (LWDS) RCRA Facility Investigation (RFI) and included in this review. These excerpts are in *italics* and precede the New Mexico Environment Department (NMED) comments.

GENERAL COMMENTS

- 1.a. **Although additional investigation is warranted, with the results of the LWDS RFI, Sandia National Laboratories/New Mexico (Sandia) has satisfactorily completed the exploratory study¹ phase of the investigation of the LWDS Environmental Restoration (ER) sites:**
- a. **Initial information on potential contaminants and hydrogeology has been gathered,**
 - b. **The sites have been sampled, and it has been determined that contamination exceeding SNL/NM's background levels for inorganic contaminants of concern (COCs) is present, and that organic contamination is present, and**
 - c. **Initial estimates of the volumes of contamination have been made.**

The results of the LWDS RFI indicate that, in some areas, additional site investigation or a final study is needed to determine the nature and extent of the contamination. But first, Sandia should compare the results of the exploratory study with NMED-approved background concentrations. Also, the potential threat to ground water from subsurface contamination should be assessed and a conceptual hydrogeologic model prepared.

Response: The LWDS RFI Work Plan, upon which the RFI report was based, was approved by the U.S. Environmental Protection Agency (EPA) on June 1, 1994. Hence, the LWDS RFI was not an "exploratory study," but rather, a full-scale field investigation of the LWDS following a regulatory-approved approach. This investigation met its primary objectives, listed on page iii of the LWDS RFI report (SNL/NM 1995a). These objectives were to:

1. Define the nature and extent of contamination at each of the ER sites that comprise the LWDS
2. Identify potential contaminant transport pathways
3. Evaluate potential risks posed by the levels of contamination identified at the LWDS
4. Provide guidance for selecting remedial alternatives at the site, if necessary.

Surface and subsurface soil samples collected during the LWDS RFI identified several inorganic constituents exceeding the NMED-approved background levels for Sandia National Laboratories/New Mexico (SNL/NM) (see response to General Comment No. 2), as well as the presence of low-level organic contamination.

¹ Barth, D.S., and Mason, B.J., Soil Sampling Quality Assurance User's Guide: US Environmental Protection Agency Report No. EPA 600/4-84-043, 104 p.

However, the LWDS risk assessment and additional risk calculations [see SNL/NM's response to Comment 10 of the EPA comments related to the LWDS risk assessment in Attachment B] indicate that these low levels of contamination do not threaten human health or the environment. Thus, SNL/NM and the Department of Energy (DOE) do not agree that additional site investigation or a final study is needed to determine the nature and extent of the contamination.

Although the NMED-approved background concentrations for SNL/NM were not available when the LWDS RFI was written, a table comparing the more recent background concentration data to the maximum concentrations of contaminants detected in LWDS soils is presented in the response to General Comment No. 2. In addition, Attachment A presents all of the soil analytical data collected during the LWDS RFI, and compares these data to the NMED-approved maximum background values for SNL/NM (where available). The tables in Attachment A are presented on diskette, with only the first pages of each table printed as hard copy to allow a regulatory quality control (QC) check for appropriate format and information content.

SNL/NM and DOE recommend No Further Action (NFA) for the LWDS surface sites. SNL/NM and DOE also recommend that the LWDS NFA request be considered separately from all present Technical Area (TA)-V groundwater contamination issues. These recommendations are based on the fact that, although contamination was detected at all three sites, contamination levels are low and in most cases barely discernible above background, when applicable. Contamination is limited to the near-surface soils in the LWDS surface impoundments, the vicinity of the LWDS drainfield, and inside the LWDS holding tanks.

Furthermore, risk calculations conducted for the LWDS surface sites indicate that the sites do not threaten human health or the environment. Calculations conducted using maximum contaminant concentration values from the three surface sites indicate a maximum hazard index of 0.4 and a cancer risk of 7.0×10^{-6} (see Risk Assessment Comment 10 in Attachment B). RESRAD simulations (see Risk Assessment Comments 9 and 11 in Attachment B) demonstrate that the LWDS surface sites will meet the proposed EPA 15 millirem/year radiation dose limit (assuming ER Site 4 is filled with 2 meters of clean soil).

Because SNL/NM and DOE intend to continue monitoring groundwater quality at the LWDS and TA-V (regardless of whether or not the NFA is approved for the LWDS surface sites), SNL/NM and DOE request that groundwater issues at LWDS and TA-V be addressed separately from the LWDS surface sites. The lack of organic contamination in soils at the LWDS sites indicates that the sites are not presently contributing to trichloroethene (TCE) contamination in groundwater at TA-V. Hence, there is no reason to further investigate these sites, in terms of how they relate to TA-V groundwater quality, and an NFA can be considered regardless of the ongoing groundwater issues.

Although the LWDS RFI is focused primarily on the LWDS ER sites and on surface contamination issues, a brief summary of the TA-V groundwater issues and information concerning the hydrogeologic conceptual model is presented below.

Trichloroethene Contamination in TA-V Groundwater

The present TA-V groundwater monitoring network consists of nine wells (Figure 1). Monitoring wells LWDS-MW1 and LWDS-MW2 were installed in 1993 and 1992, respectively, during the LWDS investigation. Monitoring wells TAV-MW1 and TAV-MW2 were installed in 1995 as part of the TA-III/V seepage pit (ER Site 275) investigation, while wells AVN-1 and AVN-2 were completed in 1995 as part of the Site-Wide Hydrogeologic Characterization (SWHC) Program. In 1997, three additional monitoring

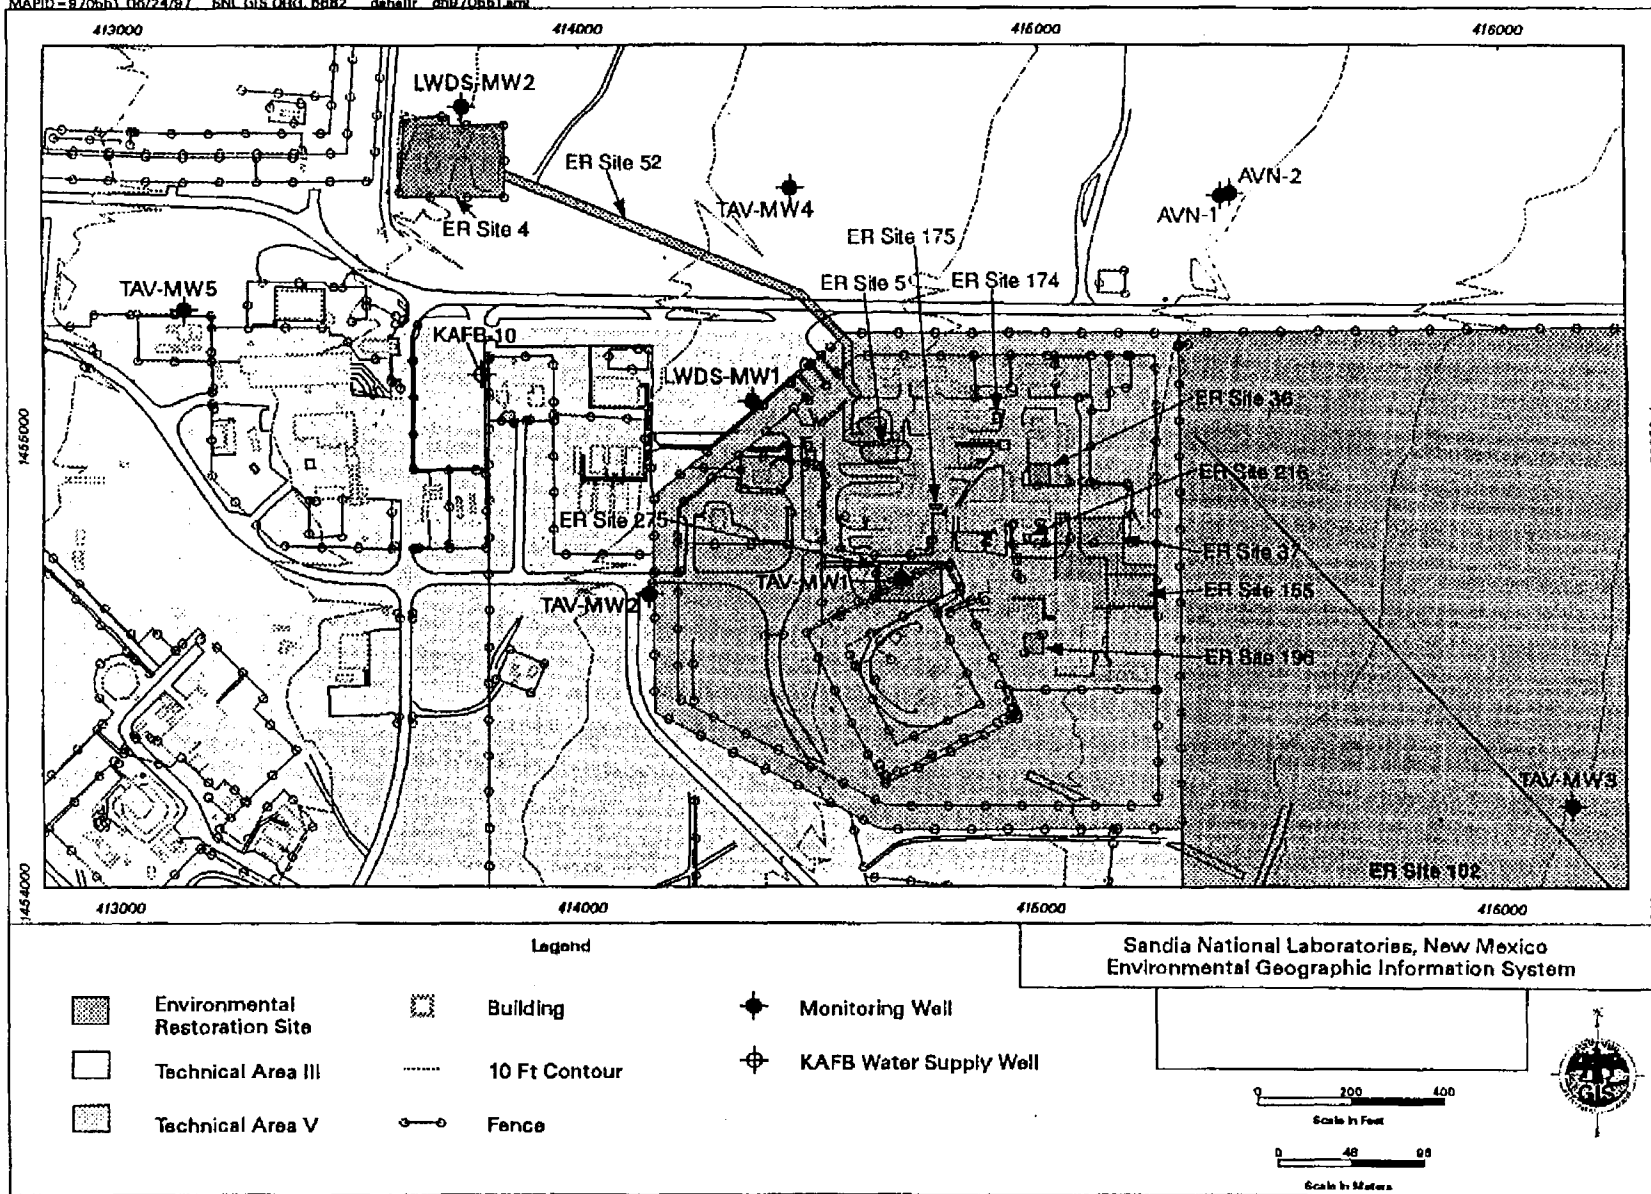

Figure 1. TA-V Monitoring Well Network.

wells (TAV-MW3, TAV-MW4, and TAV-MW5) were installed to further characterize groundwater in the vicinity of TA-V.

TCE and its degradation product, 1,2-dichloroethene (DCE), were first detected in LWDS-MW1 in November 1993 at concentrations of 6 and 1 parts per billion (ppb), respectively. TCE was later detected in monitoring well TAV-MW1 at a concentration of 1.44 ppb in December 1995. Figure 2 presents a graph of TCE concentrations with time in monitoring wells LWDS-MW1 and TAV-MW1.

In October 1995, TCE concentrations of up to 2.2 ppb were also detected in the inactive production well KAFB-10, located 600 feet west of LWDS-MW1. This well has since been plugged and abandoned to prevent cross-contamination of the deeper zones within the regional aquifer.

Hydrogeologic Conceptual Model

The TA-V hydrogeologic conceptual model continues to evolve as SNL/NM and DOE conduct additional characterization, and as more data are obtained concerning potential contaminant sources for TCE in groundwater.

The investigations conducted during RFI field work for the LWDS and the TA-III/V operating units have not conclusively identified any TCE sources in near-surface soils in the vicinity of TA-V that could account for the TCE groundwater contamination. For this reason, it is believed that the TA-V groundwater contamination may be a result of the historical liquid waste-disposal practices at the LWDS or other wastewater systems at TA-V, when liquid process-wastes that may have contained TCE were disposed of through the LWDS drainfield or the TA-V seepage pits. The six TA-V seepage pits (ER Site 275) and two nearby septic tanks received nearly all process and septic water from TA-V activities conducted from the early 1960s until 1992, when the facilities at TA-V were connected to the Albuquerque publicly-owned treatment works (POTW).

Information relevant to SNL/NM's current hydrogeologic conceptual model is briefly summarized as follows:

1. Water level data from monitoring wells in the vicinity of TA-V indicate that water levels are slightly higher than expected in LWDS-MW1. These anomalous water levels are perhaps due to regional or localized hydrogeologic conditions or to historical wastewater disposal practices in TA-V.
2. Aquifer test data from several of the TA-V monitoring wells indicate that hydraulic conductivities beneath TA-V are low. Because the potentiometric gradient beneath TA-V is relatively flat, calculations using Darcy's Law suggest that the resulting horizontal groundwater flow velocities are generally less than 25 feet per year.

Although the TCE concentrations in LWDS-MW1 exceed the EPA's drinking water maximum concentration limit (MCL) of 5 ppb, they do not pose a significant threat to human health or the environment, due to the significant distance to the nearest receptors. The nearest production well, KAFB 8, is more than 2 miles north of the contaminated TA-V wells. Groundwater modeling by the SWHC Program has predicted a travel time of approximately 100 years to the nearest Kirtland Air Force Base (KAFB) production wells (Burek and Duval 1996).

Figure 2. TCE concentrations with time in wells TAV-MW1 and LWDS-MW1 (showing error bars and the analytical methods used)

The letter adjacent to each point represents the analytical method used, as follows:

A = EPA Method 8010

B = EPA Method 8240

C = EPA Method 8260,

3. TCE has only been detected in three wells (LWDS-MW1, TAV-MW1, and KAFB-10), and the lateral extent of TCE contamination in TA-V groundwater has not been fully characterized. However, groundwater quality data from the three recently installed TA-V monitoring wells should provide valuable information concerning the lateral extent of contamination at TA-V, once these wells are sampled.
4. Aquifer transmissivity data from monitoring well AVN-1 suggests that the aquifer transmissivity is greater in the deeper zone where AVN-1 is completed than in the shallower zone where other TA-V monitoring wells are completed. Hydraulic conductivity values from TA-V monitoring wells are summarized in Table 1. The apparent increase in hydraulic conductivity with depth is consistent with aquifer test results from other wells in TA-III.
5. The vertical extent of TCE contamination in this more transmissive zone is unknown. No TCE contamination has been detected in monitoring well AVN-1, which is screened in the deeper zone. However, low levels (up to 2.2 ppb) of TCE were detected in production well KAFB-10, which was screened intermittently to a depth of 1,050 feet. This well was plugged and abandoned in 1996 to eliminate it as a potential conduit for contaminants to migrate deeper within the regional aquifer.
6. The lack of significant vadose zone contamination observed during the LWDS RFI and the modeling results of infiltration from the TA-V seepage pit (Burck and Ruskauff 1997) suggest that TCE may have migrated to groundwater through aqueous-phase rather than vapor-phase transport.

SNL/NM is currently in the process of refining this conceptual model and is evaluating other possible conceptual models of contaminant transport mechanisms at TA-V.

Table 1: Summary of Aquifer Hydraulic Conductivity Results from Pumping Tests and Slug Tests Conducted on TA-V Monitoring Wells.

Monitoring Well	Type of Test	Hydraulic Conductivity	
		(feet/minute)	(centimeters/second)
TAV-MW1	Slug Test	9.36×10^{-4}	4.75×10^{-4}
TAV-MW2	Slug Test	8.02×10^{-5}	4.07×10^{-5}
TAV-MW2	Pumping Test	6.4×10^{-5}	3.3×10^{-5}
LWDS-MW1	Slug Test	2.62×10^{-5}	1.33×10^{-5}
LWDS-MW2	Slug Test	1.65×10^{-3}	8.36×10^{-5}
AVN-1	Pumping Test	2.66×10^{-2}	1.35×10^{-2}

- 1.b. **Site characterization should include a determination of the horizontal and vertical extent of any contamination that may be present and a comparison of analytical results with background conditions, as applicable. Only after the site and any contamination have been adequately characterized can a risk assessment be made, and, if necessary, a monitoring and/or contaminant remediation system be designed and implemented.**

Response: SNL/NM has characterized the vertical and horizontal extent of contamination at the LWDS holding tanks (ER Site 52), the LWDS drainfield (ER Site 5), and the LWDS surface impoundments (ER Site 4) sufficiently to evaluate the risk and to propose NFAs for these sites. Comparison to background values, as discussed in the SNL/NM response to General Comment 2 (below) and presented in tabular form in Attachment A, supports the characterization presented in the LWDS RFI report.

SNL/NM and DOE believe that this constitutes an adequate characterization of the LWDS and that the LWDS Risk Assessment indicates that a contaminant remediation system and/or monitoring system is not necessary for surface and near-subsurface ER Sites 4, 5, and 52. TA-V groundwater issues will be dealt with separately.

2. **Tables 4-4, 4-5, and 4-6 effectively constitute a comparison of the analytical results of a composite sample for each of the three Environmental Restoration (ER) sites to background upper tolerance limits (UTLs). NMED does not believe this to be appropriate. For purposes of determining the extent of contamination and for assessing risk, Sandia should compare individual sample results for each constituent of concern (COC) to the approved UTL for that COC and incorporate this information into the results of the LWDS RFI in tabled format. These tables should also include the sample depth, location, analytical methods, method detection limits, and regulatory standards, where applicable.**

Surface plots alone (such as Figures 4-16 through 4-26), while useful, are inadequate for conceptualizing the contaminant plumes. Additional horizontal and vertical cross sections, fence diagrams, and/or pole diagrams should be constructed from the tables described above, showing the distributions of the COCs at each ER site to aid in 3-D conceptualization of the contamination. For example, comparison of sample results for ER Site 4 (from Appendix C data tables) to Sandia's background UTLs (phase 3) shows contamination extending as much as 85 ft below the surface.

Response: (It is believed that the comment refers to Tables 4-2, 4-4, and 4-6, as Table 4-5 does not discuss UTLs or statistics.) None of these three tables refers to composite samples; Tables 4-2, 4-4, and 4-6 in the RFI report compare the single maximum on-site sample results at ER Sites 52, 5, and 4 to background UTLs (at the time the RFI was written).

SNL/NM agrees with the NMED that for the purposes of determining the extent of contamination and assessing risk, SNL/NM should compare individual sample results for each COC to the approved UTL (or "hot-measurement value," see EPA 1992) for that COC. In this case, the NMED-approved maximum background concentrations are the "hot-measurement values," and hence represent the "regulatory standard." Table 2 presents a comparison of NMED-approved maximum background concentrations to the maximum concentrations detected in soils at the LWDS.

Table 2. Comparison of NMED-approved Maximum Background Concentrations to the Maximum Concentrations Detected in Soils at the LWDS.

Parameter	Units	Surface Impoundments (Site 4)	Drainfield (Site 5)	Holding Tanks (Site 52)	Highest Maximum Concentration of all Sites	NMED-Approved Maximum Background for the Southwest Supergroup
Barium	mg/kg	849	258	412	849	130
Beryllium	mg/kg	4.9	1	1.2	4.9	0.65
Cadmium	mg/kg	154	51.1	1.3	154	0.9
Chromium, Total	mg/kg	97.7	42.4	28.2	97.7	15.9
Chromium-Vi	mg/kg	11.2	NA	NA	11.2	NA
Copper	mg/kg	239	24.2	18.4	239	15.4
Lead	mg/kg	72.5	14	10.2	72.5	11.8
Nickel	mg/kg	173	13.7	15.5	173	11.5
Silver	mg/kg	90.5	NA	NA	90.5	<1
Zinc	mg/kg	198	67.3	47.3	198	62
Bismuth-212	pCi/g	2.7	1.3	1.5	2.7	NA
Bismuth-214	pCi/g	1.4	0.84	1	1.4	NA
Cesium-137	pCi/g	10.1	0.14	0.093	10.1	0.079
Cobalt-60	pCi/g	11	0.15	ND	11	NA
Lead-212	pCi/g	1.4	1.1	1	1.4	NA
Lead-214	pCi/g	1.3	1	1.2	1.3	NA
Potassium-40	pCi/g	35	19	19	35	NA
Radium-226	pCi/g	3.68	2.25	2.14	3.68	1.76
Radium-228	pCi/g	7.37	1.1	1.3	7.37	0.93
Thorium-232	pCi/g	1.18	1.1	1.3	1.3	1.01
Tritium	pCi/L	320	NA	NA	320	NA
Uranium-235	pCi/g	3	NA	NA	3	0.16
PCBs	ppb	71	NA	NA	71	NA

mg/kg = Milligrams per kilogram.

NA = Not applicable.

ND = Not detected.

pCi/g = Picocuries per gram.

pCi/L = Picocuries per liter.

ppb = Parts per billion.

Data tables that present individual sample results, including information on sample depth, location, analytical methods, and method detection limits, are included in Attachment A. These tables also include the NMED-approved background values, where available, for each constituent to allow comparison of on-site values to background.

Cross sections and surface contaminant contour plots that illustrate and depict significant findings were included in the LWDS RFI report (e.g., see Figures 4-7 through 4-11 and Figures 4-16 through 4-26). SNL/NM will review the LWDS data and propose specific cross sections to supplement these figures. SNL/NM and DOE would then like to meet with the NMED and the DOE-Oversight Bureau (OB) informally to review the proposal, and to agree on which specific cross sections should be constructed.

3. **Comments pertaining to the risk assessment have been developed by the US Environmental Protection Agency, Region 6 (EPA), and are included as an attachment to this Notice of Deficiency (NOD). Sandia should include a response to the risk assessment comments in its NOD response for the LWDS RFI Report.**

Response: SNL/NM has included their responses to the EPA risk assessment comments in Attachment B of this submittal.

SPECIFIC COMMENTS

Section 3.0 DATA EVALUATION

4. **Page 3-1, paragraph 1**

Analytical data were examined to determine whether each COC is actually present at the site as a contaminant. This involved a statistical comparison to background coupled with an examination of the spatial distribution of the constituent . . . COCs that failed the statistical comparison to background and showed a strong spatial correlation were identified as contaminants.

See General Comment No. 1.

Statistical analysis of a contaminant population is not acceptable to show that a site has been fully characterized with respect to any particular COC. Any sample collected at a Sandia ER site having a concentration exceeding the proposed 95th UTL (or 95th percentile, where applicable) is considered representative of contamination, unless:

- a. **The analytical result is shown to be in error, or**
- b. **An acceptable site-specific background investigation shows that background is naturally elevated above what was originally estimated for the site.**

Response: SNL/NM agrees that a statistical analysis of a contaminant will not necessarily show that a site has been fully characterized with respect to any particular COC. However, SNL/NM and DOE believe that the additional characterization of contaminant concentrations that are well below clean-up criteria or risk-based levels provides little value to the overall site characterization effort.

In the LWDS RFI, SNL/NM did not rely solely on statistical analyses, but also evaluated the spatial distribution of contaminants using horizontal isopleth maps and vertical cross sections. For example,

Figures 4-7 through 4-11 in the RFI report present vertical cross sections showing distributions of cadmium, beryllium, chromium, cobalt-60, and cesium-137 at the LWDS drainfield. Similarly, Figures 4-17 through 4-24 present the horizontal distributions of cadmium, chromium, copper, lead, nickel, zinc, barium, cobalt-60, cesium-137, uranium-235, and polychlorinated biphenyls (PCBs) in the LWDS surface impoundments.

Tables comparing each analytical value to the respective NMED-approved background values are provided in Attachment A. These tables allow an identification of the values that exceed the approved-background values. Combined with the cross sections (see response to General Comment 2), SNL/NM and DOE believe these data will be sufficient to document that the LWDS sites have been adequately characterized.

3.1 Summary of Quality Assurance/Quality Control Activities

5. Page 3-1, paragraph 4

Throughout the investigation, common laboratory contaminants including methylene chloride, methyl ethyl ketone (MEK), and acetone were consistently identified in both the field samples and the QC samples.

At the December 3, 1996, Sandia North/Micro-Purge™ meeting at the NMED offices in Santa Fe (attended by the US Department of Energy, Sandia, and NMED), representatives of the Hazardous and Radioactive Materials Bureau (HRMB) expressed concern about Sandia's QC problems with regard to "common laboratory contaminants." HRMB suggested that Sandia review their contract laboratories' QA/QC (quality assurance/quality control) programs and, if found deficient, find another laboratory. This issue is important because, historically, Sandia has used these compounds which, in some cases, were disposed of onto the ground and into pits, trenches, lagoons and leachfields.

Response: Common laboratory contaminants such as methylene chloride, methyl ethyl ketone, and acetone have been problematic for SNL/NM and DOE, particularly in the earlier laboratory data, and at times, made evaluating the presence of these contaminants in environmental samples difficult. SNL/NM is taking extensive steps to reduce these incidents of laboratory contamination, both in the on-site and off-site laboratories. In addition to closely evaluating the laboratories' QA/QC programs, SNL/NM also has taken the following steps:

On-site Laboratory:

At the on-site ER Chemistry Laboratory, neither acetone nor methyl ethyl ketone is used in the laboratory. Methylene chloride is used, but only in a separate room from the analytical equipment, and only under a fume hood. To prevent cross-contamination between rooms, employees using methylene chloride are not allowed to enter the laboratory where the analytical equipment for volatile organic compounds (VOCs) is located. In addition, preventative maintenance is performed daily when analyzing VOCs to prevent carryover contamination within the equipment. These measures have been very successful in reducing the amount of laboratory contamination detected in the sample results.

Off-site Laboratories:

The SNL/NM Sample Management Office conducts laboratory oversight of approved off-site laboratories through their Characterization Management Program. This program was developed under DOE Albuquerque Operations as their centralized laboratory-auditing and management oversight program. Components of this program include submitting known QA/QC samples to evaluate laboratory performance and conducting QA/QC audits of off-site laboratories on at least an annual basis.

In addition, SNL/NM requires the analysis of trip blanks for VOCs, and requires contract laboratories to run equipment blanks to identify carryover contamination. These standard QA practices are recommended by the EPA in SW-846 (EPA 1986) and allow SNL/NM and DOE to identify potential laboratory contaminants such as methylene chloride and acetone.

6. Page 3-2, paragraph 1

QA/QC procedures . . . also included . . . reviewing sample holding times, equipment rinsate, method and trip blank results, and comparing duplicate samples. . . Chromium VI was especially problematic due to the 1-day holding time which could not be met by the off-site laboratory.

Because holding times were exceeded, NMED considers that Sandia's chromium-VI values represent minimum levels only. Sandia should resample for chromium-VI, at locations where it has been determined to be a potential COC.

Response: SNL/NM erroneously assumed a 1-day holding time for chromium-VI in soils; the actual holding time for chromium-VI in soils is 28 days to extraction and 4 days after extraction (EPA 1986, Table 3-1). The chromium-VI data collected during the LWDS RFI for soils are valid and, therefore, a resampling program for chromium-VI does not appear to be necessary.

3.2 Statistical Analysis of Background

7. Page 3-2, paragraph 3

As required in the LWDS RFI work plan, a site-specific background study was also conducted at the LWDS. . . . However, the SWHC Project-determined background populations were used for data evaluation in this report, rather than the LWDS background data

Sandia should not rely solely upon regional data to make site-specific decisions. In order to make an informed evaluation of site-specific conditions, SNL/NM should include the data obtained from the LWDS background investigation.

Response: The site-specific background data obtained from the LWDS background investigation were included in Appendix C of the LWDS RFI report. These data are also presented as Table A-10 in Attachment A of this supplementary information package.

The site-specific background data were not used to identify contamination because the background soil samples did not replicate the lithologic range exhibited by environmental samples from the LWDS. The 17 surface-soil (including 1 duplicate) background samples were collected from a localized 50 by 50 foot area located 1,000 feet northeast (upwind) of the LWDS surface impoundments. The lithology of the background study site was very uniform and did not adequately represent the variable conditions observed in the surface and subsurface at the LWDS. This was confirmed using statistical tests between common elements (non-COCs) from on-site environmental samples and the LWDS background samples, which indicated that these data sets failed comparison tests.

Section 4.0 SITE-SPECIFIC RESULTS, CONCLUSIONS, AND RECOMMENDATIONS

4.1 ER Site 52 Holding Tanks

ER Site 52 consists of three buried tanks (two concrete and one steel) and associated piping. These tanks were designed to receive liquid wastes from the Sandia Engineering Reactor Facility (SERF) main reactor, experimental facilities, and support facilities located in Buildings 6580, 6581, 6582, and 6583 in TA-V between 1962 and 1971. The tanks served as holding tanks to allow short-lived radionuclides to decay before discharge to the drainfield and/or surface impoundments. Potential contaminants of concern from this waste stream include radioactive wastes in the coolant water, and organic solvents and radiochemicals from the support facilities. The primary sources of radioactivity in the liquid wastes were the short-lived activation products of the coolant water and water impurities.

4.1.2 Field Investigation

8. *Internal Contamination*, page 4-4, paragraph 5
The discharge point for the water should be specified.

Response: Page 4-1, paragraph 2 identifies the discharge points to be “the drainfield and/or surface impoundments (ER Sites 4 and 5).” A diagram of the piping associated with the surface impoundment discharge points is presented on page 4-3 (Figure 4-2). The discharge point for the drainfield is located at the east end (page 4-13, paragraph 1 in the RFI report).

As discussed on page 4-3, paragraph 3, the holding tanks are now connected to SNL/NM’s new Liquid Effluent Control System (LECS). The LECS receives and holds all TA-V process water for sampling prior to discharge to the City of Albuquerque POTW.

9. *Page 4-5, paragraph 1*
The depth of the pipe and how many pipe joints are associated with the tanks or the total piping system should be specified. Also, how the soil samples were collected as well as the sample depths should be specified.

Response: The holding tank drainline is approximately 3 feet deep. The tanks and their associated piping were built in the 1960s; the engineering diagrams were focused on the tanks and do not show individual pipe joints. It is not possible to determine the exact number of pipe joints associated with the tanks or the total piping system. The soil samples were taken in accordance with ER Field Operations Procedure (FOP) 94-52, Spade and Scoop Method for Collection of Soil Samples. Samples were collected immediately beneath the disassembled pipe (approximately 3 feet deep).

10. *Subsurface Soil*, page 4-7, paragraph 1
The boring log descriptions and photoionization detector (PID) readings associated with the borings should be included in the report.

Response: All available boring log descriptions are included with this transmittal as Attachment C.

Organic vapor screening was conducted during the LWDS field investigations primarily for health and safety purposes rather than as part of site characterization. As such, SNL/NM did not collect the instrument readings for separate reporting, and the records of such screening are dispersed among

numerous daily logs. Often, PID readings from breathing-zone monitoring were not recorded in these logs unless they were above action levels specified in the Health and Safety Plan.

This practice seems to be in general agreement with past EPA and NMED guidance to SNL/NM and DOE:

- On their Notice of Deficiency for Solid Waste Management Unit (SWMU) 79, Building 904 Septic System, the EPA questioned “the value of the organic vapor survey conducted in 1991 held at waist height” (page 7, first paragraph).
- Lloyd Aker of the NMED DOE OB discussed this issue in a November 2, 1995, letter to Benito Garcia. “Health and Safety (H&S) Survey Data - use of organic vapor screening results for H&S purposes as part of the process for determining the suitability of the site for a NFA proposal must be discontinued. Data from PID monitoring (usually at waist height) done for worker health and safety reasons are not acceptable for site characterization purposes. This information has no use in the investigative process (other than as health and safety screening information) and should not be included in any NFA proposal.” (page 4, item number 4).

All H&S records are maintained in the SNL/NM Environmental Operations Record Center and can be provided or made available for review, if necessary.

11. **Page 4-7, paragraph 1**

A map that locates the HERMES site in relation to the LWDS site should be included.

Response: Figure 4-4 (page 4-12) of the RFI report shows the locations of the High Energy Megavolt Electron Source (HERMES) Site (ER Site 36) in relation to the LWDS Holding Tanks and Drainfield, ER Sites 52 and 5.

4.1.3 Nature and Extent of Contamination

12. ***Subsurface Soil, page 4-7***

The depth of the soil sample should be included, as well as the boring log description and PID readings associated with the soil sample.

Response: The excavation soil sample was collected immediately beneath the pipe, approximately 3 feet deep. No boring log was completed for this shallow excavation, as the piping was presumably surrounded with disturbed soil and/or fill material. Please refer to the response to Specific Comment No. 10 regarding the use of H&S screening for site characterization.

13. **Page 4-8, Table 4-1, *Holding Tank Internal Sampling Results***

A table which includes the hazardous constituent results for each borehole taken under the tanks should be included. Also, the intervals the soil samples were collected from, such as 25-26 feet, etc., should be indicated.

Response: The hazardous constituent results for each borehole beneath the holding tanks are presented in Tables A-4 through A-6 in Attachment A, including all non-detect values. These tables present the results of all ER Site 5 soil analyses for metals, organics, and radionuclides. These tables also include the depths at which the samples were collected. Depth intervals are not provided on these tables, as the samples collected are basically discrete samples collected at a specific depth, rather than composited across a

continuous core section. The actual depth interval over which the samples were collected is a function of the core barrel length and the volume of soil required for laboratory analyses.

14. **Page 4-8**

All analytical results [for soil samples] were determined to indicate a lack of contamination (as discussed in Section 3.0), with the exception of the 15-ft sample from Borehole 15.

In order to properly evaluate the results of the borehole drilling and sampling, Sandia should supply cross-sections showing the angled boreholes, sampling locations, lab results, and holding tanks. This information is necessary for adequate characterization of the site.

Also, see General Comment No. 2.

Response: A cross section, as described above, will be included in the proposal for a complete cross section package to be provided later. This package will be developed in response to this request for supplemental information and will include all cross sections needed by the NMED to evaluate the LWDS data. Also, see response to General Comment No. 2.

15. **Page 4-10, Table 4-3, *Holding Tank Soil Contaminant Summary***

The maximum concentration values for all metals and the proposed background values for all metals should be included.

Response: Table 2 presents the maximum concentration values for all metals considered as COCs at ER Sites 4, 5, and 52, and the NMED-approved background values for these metals. The tables included with this response as Appendix A compare all metal and radionuclide analyses for each LWDS site to the NMED-approved background values.

4.2 ER Site 5 LWDS Drainfield

The LSDS Drainfield is buried approximately 30 feet deep and has a holding capacity of approximately 12,000 gal. It was designed to receive liquid wastes discharged from the LSDS holding tanks, and was operational from 1963 until 1967, when it collapsed. No evidence of an overflow or spill, which would have occurred in the Building 6580 basement, has been found. The only verified source of contamination in the LWDS drainfield is the discharge from the LWDS holding tanks. Several other sources, however, in the area may have contributed to soil contamination at the drainfield: ER Site 181, which was the site of a leaking underground storage tank (fuel oil) Site 36, Oil Spill - HERMES, the site of an extensive release of dielectric oil (not a hazardous waste) and possibly other hazardous constituents to the subsurface, and ER Site 275, TA-V Seepage Pits, where most of the process and septic water from TA-V are processed.

4.2.2 Field Investigation

16. ***Boreholes*, page 4-13**

The boring log descriptions and PID readings associated with the borings should be included.

A table that presents the hazardous constituent results for each borehole taken under the drainfield should be included. Also, the interval at which each soil sample was collected should be indicated.

Response: All available boring log descriptions are included with this transmittal as Attachment C. Please refer to the response to Comment No. 10 regarding the use of H&S screening for site characterization.

Tables of all environmental sampling results for ER Site 5, including both hazardous and radioactive constituents, are presented in Attachment A as Tables A-4 and A-6. See the response to Specific Comment No. 13 regarding depth intervals of the samples.

17. *Monitor Well Installation, page 4-15*

The direction that ground water is moving should be indicated in the revised report. Also, the boring log description for this well should be included.

Response: Section 2.5 of the RFI report, "Hydrogeology," discusses the direction of groundwater movement. In general, groundwater flows west / northwest beneath TA-III (Reeder et al. 1967; Kues 1987).

Figure 2-2 in the LWDS RFI report presents the boring log for LWDS-MW1, including abbreviated lithologic and geophysical logs and a stratigraphic column for LWDS-MW1. Detailed lithologic descriptions for LWDS-MW1 and LWDS-MW2 (developed by the USGS) were submitted to the NMED in September 1994 (Cox 1994). These lithologic descriptions are also included in Attachment C of this submittal.

18. *Ground-Water Sampling, page 4-16, paragraph 2*

All past sampling results should be included in the revised report.

Response: Groundwater data from the TA-V monitoring wells are submitted on an annual basis to the NMED, EPA, and DOE in the annual groundwater monitoring reports, prepared by SNL/NM's Groundwater Protection Program. The TA-V groundwater sampling results (from the 1993, 1994, 1995, and 1996 Annual Groundwater Monitoring Reports [SNL/NM 1994, 1995b, 1996, and 1997]) are reproduced in Attachment D for ease of review.

4.2.3 Nature and Extent of Contamination, page 4-16

19. *Page 4-16*

The volatile and semivolatile analytical results should be included in the revised report. Trip blank results should also be included.

Response: The volatile and semivolatile analytical results for all LWDS sites are included in Tables A-2, A-5, and A-8 in Attachment A. All trip blank and equipment blank results for ER Sites 4, 5, and 52 are presented in Table A-13 of Attachment A.

20. *Page 4-16, paragraph 3*

The contamination is limited to the drainfield and the surrounding soil, and no contamination has been detected below 45 ft. Organic contaminants, principally TCE, are present in levels above federal maximum concentration limits (MCLs) in the drainfield monitor well. The LWDS has been ruled out as the source of this contamination due to the absence of TCE at the site.

NMED considers that the site has not been sufficiently characterized. Review of Figure 4-5, Table 4-4, and Figures 4-7, 4-8, 4-9, 4-10, and 4-11 indicates that the bulk of the contaminants are centrally located along the axis of the drainfield and extends horizontally for an unknown distance away from the drainfield. Wastewater entered the drainfield in volumes large enough to wash out the drainfield and cause its collapse. This large volume of wastewater

may have flushed contaminants, at higher concentrations than the concentrations observed in borehole samples and in the PETREX Soil Vapor Survey, away from the drainfield location, as suggested by analytical results from Borehole-12 and Borehole-14. Therefore, ER Site 5 LWDS Drainfield cannot be ruled out as a potential source of TCE contamination in ground water.

Two additional boreholes, one north and one south of the center of the leachfield, should be drilled and sampled by SNL/NM to determine primarily, but not exclusively, the horizontal extent of the contaminated soils. The vertical extent of this contamination should also be determined. SNL/NM should attempt to locate each borehole within the leachfield effluent wetting front. Each borehole should be of sufficient depth to extend beneath the contaminant plume.

Response: A conceptual model for contaminant transport at ER Site 5 that includes contaminant flushing from the discharge area and the subsequent accumulation or residence of high levels of constituents that are geographically removed from ER Site 5 was not considered in the RFI report.

Based on the discharge history and past operations at TA-V, it is highly likely that solvents and other contaminants were repeatedly disposed of into the liquid effluent systems associated with the LWDS. SNL/NM and DOE expect that these disposal practices did not change significantly until after the 1967 collapse and decommissioning of the drainfield. Under this scenario, there is no major source of clean water available to completely flush previously-disposed-of contaminants to remote locations.

In considering that the horizontal extent of contamination might increase with distance away from the drainfield boundaries, again a large source of clean water must be presumed to be available. SNL/NM and DOE believe that the site history does not support this presumption. In addition, the presence of a wetting front that extends laterally from the boundaries of the actual drainfield is presumed as a potential lateral transport mechanism for contaminants. In previous discussions with SNL/NM and DOE regarding possible septic tank wetting fronts, this lateral spreading of fluids was considered by NMED to be an unimportant transport mechanism for contaminants.

Although the past disposal of TCE is likely to have occurred during the operation of the LWDS drainfield, ER Site 5 (the drainfield) can be ruled out as a continuing source of TCE to the environment.

For these reasons, SNL/NM and DOE believe that the most contaminated areas at ER Site 5 have already been sampled, and the contaminant concentration data indicate that these levels of contaminants do not pose a threat to human health or the environment. Hence, SNL/NM and DOE recommend an NFA for ER Site 5 in the LWDS RFI report (SNL/NM 1995a).

21. *Ground Water, page 4-20*

Before the impact or potential impact to the environment and ground water can be evaluated, NMED needs to review laboratory analytical results for ground water samples at LWDS-MW1, as well as results from samples of other media (e.g., soils). Groundwater data should be supplied with this report in tabled format. This table should include method detection limits, the background 95th UTL for naturally occurring COCs, and applicable Federal Maximum Concentration Limits (MCLs) and/or New Mexico Water Quality Control Commission standards, whichever are more stringent.

Response: The TA-V groundwater sampling results from SNL/NM's 1993, 1994, 1995, and 1996 Annual Groundwater Monitoring Reports are presented in tabular format in Attachment D. These tables (except for the 1993 data) include the detection limits, MCLs, and the New Mexico groundwater standards.

22. **Pages 4-21 - 4-22**

TCE has been detected in all samples since September 1993 at concentrations from 12 to 16 ppb, and other organic contaminants are sometimes detected.

The other organic contaminants detected should be included.

Response: The only other organic contaminant definitively identified in TA-V groundwater is 1,1-DCE, a degradation product of TCE. However, low levels of other VOCs have occasionally been reported for TA-V groundwater samples, but these results are believed to represent laboratory contamination. In addition, nitrates at or exceeding the MCL have been detected in TA-V groundwater. The TA-V groundwater sampling results from the 1993, 1994, 1995, and 1996 Annual Groundwater Monitoring Reports are presented in Attachment D. Background values for VOCs are assumed to be zero, as VOCs are not naturally occurring.

4.3 ER Site 4 LWDS Surface Impoundments

ER Site 4 consists of two unlined surface impoundments constructed in 1967 and 1970 after the collapse of the LWDS Drainfield. They were used for the disposal of primary coolant water from the SERF, and the potentially contaminated waste water from experiments and operations in the SERF buildings. On at least one occasion, waste oil and resin beads were disposed of in the surface impoundments. Approximately 12 million gal of waste water containing approximately 14 Ci of measured radioactivity were discharged between 1967 and 1971. The short half-life activation products have decayed and potential residual contamination consists of fission products, other radionuclides, and laboratory solvents. PCBs were identified in the southwest corner of Impoundment 2.

ER Site 4 LWDS Surface Impoundments

23. ***Previous Investigations, page 4-25***

All previous soil sampling analyses should be included in the revised report.

Response: The one PCB detection of 24.6 parts per million (ppm) described in this section represents the only previous soil sampling analysis for hazardous constituents. As stated in the RFI report, water, soil, and sludge sampling events were sporadic and poorly-documented. Data related to this previous sampling were not located. Therefore, a more extensive investigation was performed for ER Site 4 than might otherwise have been necessary.

24. ***Field Investigation, page 4-26***

Did Sandia determine whether the piping from the tanks to the surface impoundments was leaking?

Response: The drainline piping between the holding tanks (ER Site 52) and the drainfield (ER Site 4) was incorporated into the ER Site 52 investigation. One section of the piping was chosen for close examination as a "worst-case" scenario. The piping was determined to be structurally sound and leak free, and it contained no detectable contamination.

25. **Monitor Well Installation, page 4-32**

Sandia should include the direction that ground water is moving in the revised report as well as the boring log description for this well.

Response: See SNL/NM's Response to Specific Comment No. 17 concerning the groundwater flow direction in the vicinity of LWDS-MW2.

Figure 2-2 in the LWDS RFI report presents the abbreviated lithologic and geophysical logs and stratigraphic column for LWDS-MW2. Detailed lithologic descriptions for LWDS-MW2 (developed by the USGS) were originally submitted to the NMED in September 1994 (Cox 1994) and are also included in Attachment C of this submittal.

26. **Ground-Water Sampling, page 4-32**

See Comment No. 10.

Response: SNL/NM believes this comment should have referred to Specific Comment No. 18 rather than Specific Comment No. 10. Therefore, see response to Specific Comment No. 18.

27. **Page 4-32**

Sandia should include all past sampling results in the revised RFI Report.

Response: All past sampling results for the LWDS surface impoundments are included in Tables A-1, A-2, and A-3 in Attachment A.

28. **Metals, page 4-33, paragraph 2**

Three chromium-VI results were slightly above background. . . . In many cases, the maximum measured concentration was less than background UTL. However, a spatial analysis showing a consistent grouping would indicate anthropogenic contribution. The opposite case was also true. A maximum concentration exceeding the background UTL did not necessarily indicate contamination.

NMED is not aware that chromium-VI occurs naturally at Kirtland Air Force Base (KAFB). Sandia should submit documentation describing localities and conditions where chromium-VI might occur naturally in the KAFB area.

Response: SNL/NM has reviewed the text on page 4-33, paragraph 2, and it does not state that "chromium-VI results were . . . above background." Rather, the text states, "Three chromium-VI results were slightly above the detection limit." The text appears to have been misquoted in the comment.

29. **Page 4-33**

Sandia has already acknowledged that samples for chromium-VI analysis were held past the 1-day holding time. Sandia should resample and analyze for chromium-VI.

Response: SNL/NM erroneously reported that the chromium-VI samples were held past their holding times. All chromium-VI data for soils in the LWDS RFI report are valid. See response to Specific Comment No. 6.

30. Page 4-33
Sandia should include the analytical results for each borehole in the revised report.

Response: All analytical results for each borehole drilled at the LWDS surface impoundments are presented in Tables A-1, A-2, and A-3 in Attachment A.

31. *Polychlorinated Biphenyls*, page 4-41
Sandia must contact Ms. Lou Roberts, US EPA Region 6 TSCA contact, regarding the polychlorinated biphenyl) PCB contamination. She can be reached at (214) 665-7579.

Response: Ms. Lou Roberts was contacted regarding the PCB contamination on February 20, 1996. The highest concentration measured was only 71 ppb, not 71 ppm as reported to Ms. Roberts by Mr. Mayer. Ms. Roberts indicated that 71 ppb in soil is below concern to her office.

32. Appendix B, *PRECIS INPUT PARAMETERS*, page B-1
Sandia should include the detection limits for the semivolatile and volatile analytical methods.

Response: In general, volatile analyses were conducted by EPA Method 8240, with detection limits of 5 to 10 ppb, while semivolatile analyses were conducted by EPA Method 8270, with a detection limit of 330 ppb. Specific detection limits for individual samples are presented in the data tables in Attachment A.

ATTACHMENT A

Soil Analytical Data from the LWDS

(in Electronic Format)

Attachment A

This attachment contains all of the soil analytical data collected during the Liquid Waste Disposal System (LWDS) RCRA Facility Investigation and the analysis of trip blanks and equipment blanks. The data are presented on diskette as Microsoft Excel[®] worksheets. Due to the extensive quantity of the data collected, the tables are rather lengthy and are not printed in full in this attachment. Rather, only the first page of each table is printed to allow a quick overview of the contents of each table.

This attachment contains the following tables, which are organized by LWDS Environmental Restoration site number and by the category of the analyte (i.e., metals, organics, and radionuclides):

Table A-1	Metals Analyses of Soil Samples from ER Site 4
Table A-2	Organics Analyses of Soil Samples from ER Site 4
Table A-3	Radionuclide Analyses of Soil Samples from ER Site 4
Table A-4	Metals Analyses of Soil Samples from ER Site 5
Table A-5	Organics Analyses of Soil Samples from ER Site 5
Table A-6	Radionuclide Analyses of Soil Samples from ER Site 5
Table A-7	Metals Analyses of Soil Samples from ER Site 52
Table A-8	Organics Analyses of Soil Samples from ER Site 52
Table A-9	Radionuclide Analyses of Soil Samples from ER Site 52
Table A-10	Metals Analyses of Soil Samples from the LWDS Background Study
Table A-11	Organics Analyses of Soil Samples from the LWDS Background Study
Table A-12	Radionuclide Analyses of Soil Samples from the LWDS Background Study
Table A-13	Trip Blank and Equipment Blank Results for ER Sites 4, 5, and 52

Table A-1. Metals analyses of soil samples from ER Site 4.
